THE

JOURNAL OF HORTICULTURE,

COTTAGE GARDENER,

AND

HOME FARMER.

A CHRONICLE OF COUNTRY PURSUITS AND COUNTRY LIFE, INCLUDING BEE-KEEPING.

CONDUCTED BY

ROBERT HOGG, LL.D., F.L.S.

Established

in 1848.

VOLUME VIII. THIRD SERIES.

JANUARY TO JUNE, 1884.

LONDON:

PUBLISHED FOR THE PROPRIETOR, 171, FLEET STREET.

1884.

LONDON:
PRINTED AT THE JOURNAL OF HORTICULTURE OFFICE,
171, FLEET STREET.

TO OUR READERS.

AGAIN it is our pleasure, on the addition of one more to the many preceding volumes of this Journal, to express our appreciation of the work of our many friends who have assisted so effectively in its preparation.

In congratulating them on the excellence of their productions—the reflex of sound and successful practice—we also congratulate ourselves that, with one lamentable exception, the late Mr. Alexander Honeyman, our old friends remain with us; also that new ones of promise are enrolled in our ranks.

It will not be inappropriate to refer here to the great bond of sympathy that exists between the readers, writers, and Editors of this Journal, as was exemplified in connection with the melancholy occurrence above alluded to, and we rejoice to state that the widow and fatherless have been cheered and benefited during the past half year.

We can state nothing that can be more acceptable to all than that Mrs. Honeyman has been placed in a position to bring up her family in a befitting manner, mainly by the aid of the sum that was contributed—namely, £144 5s. 4d.

We have peculiar pleasure in making this announcement, as it enables us to feel that our pages have been useful, and we thank one and all equally and heartily—the students in horticulture and frugal self-sacrificing gardeners for their mites, and the affluent for their substantial offerings.

While the past has not proved barren, we are confident there is “good in the future”—mutual help in any difficulty that may arise, and the communication of knowledge that will render our work, as heretofore, satisfactory to ourselves and to our numerous and discriminating constituents.

INDEX.

—0—

- ABUTILONS IN SMALL POTS, 231; grafted, 306; culture of, 476
- Achimenes, propagating, 332
- Adiantum ciliatum, 130; A. rubellum, 133; best species of, 184; and Gymnogrammas at Kew, 188; A. rhodophyllum, 246; notes on species of, 278
- Azides Lawrencei, high price of, 82
- Aleyrodes vaporariorum, 403, 423
- Allamandas, culture of, 312
- Allium neapolitanum, 353
- Alocasias, notes on, 94
- Alpine and rocky plants, 89
- Amaryllises from seed, 96; General Graham and Ne Plus Ultra, 214; at Chelsea, new varieties, 229; Col. Burnaby, Mrs. Shirley Hibberd, and Sir Redvers Buller, certificated, 249; drying, 254; history of, hybridising, 277; Mars, 287; Virgo and Zitella, 291; Adelina Patti, 304; Countess of Rosebery, 307; Aleyone, 327; culture, 332, 419; at Holloway, 348; formosissima, 374
- Amateur, definition of, 549, 359, 384, 399, 419
- Anemones, single, 226; notes on, 322; raising from seed, 334; stellata flore-pleno, 343; notes on species of, 399; disease in garden, 505; coronaria, double varieties, 444
- Angles of roofs, determining, 118
- Angræcum fastuosum, 326
- Anobium striatum, 455
- Anomatheca cruenta from seed, 62
- Annuals, sowing, 313
- Antennaria tomentosa, 344
- Aphelandra anrantiaea, 24; Roezlii, 103
- Apple Chri Tall, 16
- Apples and cider-making, 185
- Apples, moss and lichens on trees, 26; Norfolk Stone Pippin, 29; keeping, 32; Gloria Mundi, 54; American importations of, 105; Annie Elizabeth, 146; Mr. Nield's paper on, extent of culture, 176; in sand and charcoal, 214; High Canons, certificated, 325; trees, espalier, 437; for ornamental purposes, 442
- Apricots, insects on, 413
- Aralias, species and propagation of, 77
- Aristea capitata, 486
- Artichokes, history of, 381
- Asparagus-beetle, 112; spring treatment, 202; plumosus, 299; salting beds, 334, 393
- Aspidias, 461
- Asplenium Ruta-muraria, 33; horridum, 406
- Astrocaryum mexicanum, 4
- Atkins, death of Mr. James, 304
- Aubergines, 7
- Auricula, Rochdale Society's meeting, 63; destroying aphids on roots, 74; ton-dressing, 111; notes on, 214; Hetty Dean, 249; a review, 317; early shows of, National Show, 327; old essay on, 334; at South Kensington, 345; Mrs. Horner, 350; Society's (National) Northern Show, 355; Rochdale, 371; and Polyanthus, culture, 391; Alpine and seedlings, 394; potting, 404; varieties, 408; in Scotland, 445; small pots for, woolly aphids, 464; alpine, 468; in Ireland, 515
- Australian horticulture, 484
- Azaleas, reporting, 176; restoring neglected, 178; potting, 198; culture of, Little Beauty, 213; Mrs. Heaver, 214; choice Ghent varieties, amœna Caldwelli, 243; Van Houtte, certificated, at Shircliffe Hill, 290; treatment after flowering, 334; hardy, 429
- Azara microphylla, 208, 227
- BALFOUR, death of Dr., 125
- Balsams, culture, 312
- Batemannias and cool treatment, 49
- Bath Show, 406
- Bath and West of England Show, 450, 457
- Bauera rubioides, 189
- Beans, Kidney, in pots, 137; Girtford Runner, 242
- Beaucarnea recurvata, 170
- Bedding plants from seeds and cuttings, 116; propagating, 234
- Bees—queen battles, 18; the comingbee, 19; practical management of, 32; starting Ligurian stock, swarming & non-swarming, 53; Syrian, 73; swarming and non-swarming, 116; effects of mild weather, 137; curing foul brood, 137; feeding, 157; seasonable notes on, 175; hives and quilts, 178; Ligurians, 197, 217; seasonable notes, 234; estimates of Ligurians, what age do they gather honey? 233; seasonable notes on, 272; transferring, 273; American smoker for, 275; spring feeding, 292; Ligurian and Syrian bees, 293; experiences in keeping, Cyprian and Syrian, 313; seasonable notes on, 332; various phenomena, Syrians and Ligurians, 352; spring prospects, 372; bees and flowers, Syrian and black bees, 373; hunger; swarms, fertile workers, foreign bees, 392; vicious, stings, exhausting queens, near-sighted, Syrians & Blacks, 412; foul brood, floors and ventilation, Ligurians, 432; supering hives, vicious bees, fertile workers and queens in worker cells, 433; swarming and supering, Cyprians, Syrians, and foul brood, 454; seasonable notes on, fertile workers, 474; preparing stocks, 495; artificial swarms, lateral slides, 497; deposition of queens, Stewarton hives, 519; amateur's guide to bee-keeping, 520
- Beet, history of, 50
- Begonia hybridising, 2; tuberous, starting, 138; for bedding, 158; Carrieri, 213; culture of, manicata, 342; preparing Tuberous for beds, 352; useful, 519
- Belvoir, spring gardening at, 386
- Benevolent Gardeners' (Royal) Society and Mr. Divers, 208; special appeal, 324
- Bertolonias, culture of, 340
- Birds and fruit buds, 20
- Blue flowers, 407
- Boehmeria nivea, hardness of, 6
- Bog gardens, 463
- Books—review of "Every Day in the Country," 63; review of "The English Flower Garden," 93; for gardeners, 170; review of "A Guide to Methods of Insect Life," 106; review of "Profitable Fruit Farming," 147; "Mawley's Weather of 1883," 207; "Carter's Practical Gardener," 226; "Dictionary of Gardening," 324; "Cassell's Popular Gardening," "Dictionary of Gardening," 363
- Borneo, Dr. Houghton's lecture on, 48
- Borecole, Read's Hearting, 82
- Botanic (Royal) Society's Spring Show, 331; Summer Show, 409, 493
- Bougainvillea glabra culture, 196
- Bournemouth, notes from, 422
- Bouvardias, culture of, 61, 124
- Briars as tree-protectors, 178
- Bristol Gardens, Brentrey House, 71; Henbury Hill, 215
- Bristol Spring Show, 247
- Broccoli, Snow's Winter White, 44; Purple Sprouting, 301; culture and varieties of, 357; Gilbert's Late Queen, 439
- Bromeliads at Kew, 6
- Browallia Jamesoni, 213, 285
- Brussels Sprouts, May's Northau, 147; large & small, 240
- Bulbocodium trigynum and Merendera caucasica, 6
- Bulbs, half-hardy, 507
- CABBAGES, notes on, 47; Eliam's Early, 362
- Cactaceans plants, Mexican Cacti and Succulent House at Kew, 41; distribution and history of, 42; Mamillarias, 85; notes on culture and propagation, classification—Melo-cactus, 123; plants, 320, 341, 404, 420; Cereuses, 492
- Calabash Tree, 96
- Calanthes, 31; Veltheil, varieties of, 142; discolor, 325; culture of, 372
- Calceolarias, 32; at London-derry, 382; at Bedford Hill House, 383
- California, enterprise in, Yosemite Valley, 108; Coniferae, 487
- Calochortus Benthami, 451
- Caltha purpurascens, 323
- Camellias, restoring unhealthy, 178; potting, 198; leaves scorched, 521
- Campanulas, culture, 391
- Canker in Apple trees and fungus, 290
- Carnation and Picotee election, polling, 64, 90, 111, 129, 152, 169, 189; good varieties and culture for winter, 9, 19; winter-flowering, 47; The Queen, 63; C. Souvenir de la Malmaison, 132, 253; culture of for winter, good varieties of, 257; selection of, 315; for winter, 380; culture, 391; exhibiting, 451, 471
- Carnivorous plant, a, 426
- Carrot maggot, the, 378
- Carrot, history of, 490; Early Nantes, 503
- Carpet bed design, 456; planting a, 434
- Catalpa wood, 117
- Caterpillars, a plague of, 487
- Cattleya Percivaliana, 30; Percivaliana alba, 135; Trianae splendissima, 213; C. Trianae Leana, 249, 268; Skinneri at Elmers, 339; culture of, 372; Mossiae, C. intermedia, 461; at Southport, 509
- Cauliflowers, summer and autumn, 60; German export of, 106
- Ceanothus Veitchianus, 423
- Cedars Gardens, Lee, 16
- Celery culture in America, 42; fly, 113; blanching with leaves, 280; history of, 281; bleaching, 434; culture, 460; planting and earthing, 489
- Centradenia rosea, 288
- Cereuses, notes on, 404; Macdonaldia, 464
- Cestrum vespertinum, 182; aurantiacum, 488
- Ceylon Botanic Gardens, 83
- Chatsworth, Mr. Thomas's appointment to, 146
- Cherries, forcing temperature, 17; house, work in, 39, 473
- Chestnut, large specimen at Moncreiffe, 424
- Chinese Grass, uses of, 63
- Chionodoxa Lucilla, 206; in Ireland, 226; C. nana and C. sarniensis, 284; estimate of species, 323
- Chloride of potash, 545
- Chlorophyll, deoxidisation of, 30
- Choisya ternata, 474
- Chon de Burghley, 4, 110, 125, 363; atness of, 166
- Choisya ternata, planting out, 497
- Chrysanthemums—sport from Empress, 6; late, 24; altering names of, 48; origin of Lord Alcester, 83; prizes for at Kingston, 105; prizes for early, 110; late flowering, 128; catalogue of, 188; stopping and training, 218; layering, 254; in tubs, 231; National Society's schedule, 285; in April, 289; soil for, 375, 394
- Cibotium Schiedei, 105
- Cinerarias Lottie Williams and Great Eastern, 135; Polly Charming, Royal Standard, and Challenger, 214; Rosy Morn, 348
- Clematis coccinea, 208
- Clerodendrons, time for growing, 117; Balfourianum, 19
- Clanthus Dampieri, 81; puniceus, 228
- Climate, observations on the English, 385
- Climbers for conservatory, 21; pruning hardy, 156; for greenhouse, 393
- Cockscombs, culture of, 391
- Cocoa Plum, 51
- Cocoa plant, fruiting of at Regent's Park, 362
- Coburgia incarnata, 408
- Cologyne cristata culture, 280
- Coffea arabica at Kew, 263
- Colchicums, 6
- Conifers, heights of, 126
- Conservatory, the, 31; arrangements of plants in, 75; Mr. Winterburn's prize paper on furnishing, a, 211; its inmates, 308
- Controversy, 83
- Cornwall, exotic plants in, 384, 425, 442, 434
- Cranston's Nursery sick fund, 242; death of Mr. T., 402
- Creosote Plant, 284; for Hop poles, 456
- Crinodendron Hookerianum, 287
- Crimums, notes on species of, 172, 191
- Crocuses, species of, 114
- Crotons, Mr. Ranger's paper on, 23; species of, 30; culture of, 115
- Crystal Palace, shows of the season at, 63, 242
- Cucumbers—raising plants, 17; temperatures for, 74; in pots and beds, 115; culture, 196; forcing, 312; culture of, 372; withering, 414; liquid manure for, 434; gumming, 455; diseased, 476; fruit disease and remedy, 481, 507
- Cuphea platycentra for bedding, 434
- Current-bnd mite, 165, 184, 208
- Currents, summer pruning, 497
- Current topics, 462, 504
- Cyclamen Crinum Beauty, 30; fine specimen of, 146; Dame Blanche and giganteum delicatum, 135; Princess Ida, 213; persicum, culture of, 311
- Cypripedium—Lecanum, 30; venustum, 52; Spicerianum, temperature for, 142; villosum, 203; caudatum, 281; ciliolare, 290; niveum culture, 339; hybrids of tabulated, 362; caudatum, fine flowers of, 444; hardy, 506
- Cyrtanthus Mackenii, 461
- Cytisus Adami, 456
- DADDY LONGLEGS IN Regent's Park, 207
- Daffodils, similarity of species, 259
- Dahlias, starting, 138; preserving tubers of, 353; bouquet, 393; planting single, 434; Scarlet Gem, 444
- Daisies, double, varieties of, 375
- Daphne indica, propagating, 314
- Davallia hemiptera, 131; Mariest stricta, 290
- Davenport, Mr. James, death of, 444
- Decaisnea insignis, 69
- Delphinium nudicaule, 62, 90
- Dendrobiums, notes on, 18; moniliforme, 80; Hillii, 142; nobile not flowering, 198; in-teolum and Wardianum, 203; cutting down, 204; Fend-leyanum giganteum, 213, 240; cutting down, nobile, 240; pruning, 31; nobile, pruning, 324; pruning, 339, 358; treatment in spring, 372; Devonianum, 330, 461; Parishii, pulchellum, 462
- Dendrochilum, 339
- Dentaria polyphylla, 147
- Derbyshire, a ramble in, 422
- Deutzias, propagating, 234
- Diaries for gardeners, 170
- Dieffenbachia Jenmani, 30
- Digging—a chapter for beginners, 162
- Digging, method of, 184; in spring, 404
- Dioscorea Batatas culture, 335
- Disa grandiflora, culture of, 280, 303
- Disocactus insignis, 404
- Dondia epipactis, 206
- Dracenas, culture of, 115; D. Goldiana, 132
- Dublin Show, 408
- Dun-dec International Show, 62
- Duneevan, notes at, 508
- EALING HORTICULTURAL Society's report, 126
- Echeveria retusa, 165, 195
- Echinocactus, culture and species of, 320; Visnaga, notes on species, 341
- Edelweiss culture, 54
- Edinburgh Spring Show, 288
- Endive, improved Batavian, 108; hardness of Batavian, 146
- Engelmann, death of Dr., 207
- Epacris Diadem and The Premier, 135; treatment of, 453
- Ericas and Epacris, pruning and potting, 176; culture of winter-flowering, 297; australis, 343; repotting, 354
- Eryngium, notes on, 70
- Eucalyptus in Ireland, 514
- Eucharis amazonica, 14, 92, 286, 394; E. Sanderiana, 44
- Euphorbia jacquiniiflora, culture of, 432
- FARM—retrospect of in 1883, 21; new and improved agricultural machinery, 33, 55; management of Alderney cows, 56; Welsh breed of cattle, 75; manures for pastures and cereals, 76; Welsh cattle, sowing seeds for pasture, 98; Welsh cattle, 119; Grass seeds for permanent pasture, 139; Channel Island cattle, 140; Alderney cows, 140; management of cows, 140; seeds for laying down pasture, 159; artificial manuring, 160; seeds for permanent pastures on different soils, 179; grass seeds for permanent pasture in light and strong soils, 199; Rye Grass, 200; Grass seeds for various soils, 219; Grass seeds for alternate husbandry, 237; mildew in Wheat, 256, 275, 295; improving the supply of butter, 315, 335, 355; Guernsey cows, 336; Shropshire sheep, 375, 394, 415; arable and pasture farming, 435; Bath and West of England Society's Show, Channel Island Cattle, 436; arable and pasture farming, 437; British Goat Society, seed stands at Manchester, 458; arable and

FARM—continued—

pasture farms, 477; white scour in calves, Kohl Rabi, culture of, 478; arable and pasture farming, 499; Longhorn Cattle, homes for cows and calves, 521
 Fernery, a cool at Streatham, 304; indoor, 475
 Ferns for heated fernery, 96; Mr. Birkenhead's paper, 102, 129, 470
 Fig culture in the open air, 121, 390, 473; forcing, 291
 Floral societies, special, 88, 104, 128, 149
 Florists' flowers, notes on, 110, 404
 Flower-farming in New York, 82
 Flower beds, planting, 467
 Flower garden, preparing for, 351
 Flower pots, glazed, 128, 143; painted & glazed, 163, 186
 Flowers—earliness of in the open air, 24, 26; cutting and arrangement of, 91; sending by post, 165; the manufacture of artificial, 324; hardy, in America, 363; packing, 413; amongst the, 502
 Food plants insects injurious to, 445
 Forest trees, mineral requirements of, 383
 Forests of Europe, 509
 Forestry (International) Exhibition, 167
 Forsythia suspensa, 243

 Isoplepis gracilis culture, 384
 Ivy on walls, 206; pruning, 509
 Ixias, varieties of, 471
 Ixoras, culture, 196

JAMBOSA ACIDA, 135, 147

Jam, extent of manufacture 127
 Justicia flavicoma, 105

KALOSANTHES, CULTURE OF,

332
 Kew, new bulb garden at, 7; young men's rooms, 11, 29, 46; rocky, 246; report on Royal Gardens at, 310; picture gallery at, 323; notes at, 487
 Kitchen garden, work in the, 371, 452; rotation of crops, prizes for essay on, 383

LELIA ANCEPS PERCIVALI-

ana, 30; Williamsiana, 135; anceps var., 240; calistoglossa, 249
 Lapagerias, propagating, 74; rosea, 228
 Larrea mexicana, 284
 Lasiantha macrantha floribunda, 104
 Lastrea Richardsii multifida, 103
 Lawns, management of, 197

Lawn tennis ground, making, 413
 Lemon, Bijou, 26
 Lemon oil as an insecticide, 507
 Leontice altaica, 206
 Lettuce, insect enemies of, 329
 Leuchtenbergia principis, 190
 Leucolium vernum, 26; L. euphraticum, 226
 Lilioms in shrubberies, 37; in orders, 91; auratum, culture of, 301; longiflorum var. Harvii, 468, 480
 Lily of the Valley, forcing, 15, 214; the Bermuda, 48
 Lissocilus giganteus at home, 325
 Lime in fruit borders, 202
 Lime water for removing worms, 198
 Liverpool Horticultural Association, 106; Spring Show, 244
 Lobelias, propagation and culture of, 115
 London parks and commons, cost of, 487
 Longford Castle, conservatory at, 15
 Lonicea Standishii, 42
 Lotus Peltorhynchus, 69

MAGNOLIA CONSPICUA, 227, 256,

293, 304
 Mamillarias, species of, 87
 Manchester Gardeners' Improvement Society, 6, 209
 Manchester Show, 448
 Mangosteen, 54
 Manures, relative value of, 33; their action, 203; formula of for plants in pots, 286; liquid, 305; (yard) and wood ashes, relative value of, 340; liquid and artificial, 417
 Market growers, 393
 Market measures, 493
 Marigolds, Marsh, 503
 Masdevallias, spot on, 90; destroying, 125
 Mathison, death of Mr., 226
 Maule, Mr. H. J., death of, 383
 Maxillaria pieta, 18; Harrisoni, 509
 Mealy bug & tan, 2
 Medinilla Curtisii, 386
 Melons, shading, 33; for frame culture, 75; in pots, 138; culture, 196; forcing, 312; culture of, 372; setting, 374; second crops of, 434; red spider on, 456; support, 467; Chalfont Park Favourite, 487; canker, 498; cankered, alum for, 510; sweating, 520
 Merendera sobolifera, 114
 Meteorological Society's annual meeting, 69, 248, 383, 424, 514
 Meteorological observations in January, 126, 188; great storm of January, 193
 Mignonette, new American, 103
 Millepedes, destroying, 198; a plague of, 224; destroying in soil, 354
 Milner, death of Mr., 283
 Mistletoe, propagating, 215
 Mitaria coccinea, 485
 Moles, catching, 44, 120
 Morina Coulteriana, 69
 Mowing, 298
 Mulching and top-dressing, 459, and watering, 480
 Muscari moschatum major and atlanticum, 260; species of, 369
 Muscums, origin of at Kew, 126
 Mushroom spawn making, 55; novel culture of, 146; Mr. Walker's paper on, French and English, 167; heds in a shed, 198; spawning beds, 254; in moss litter, 274; beds, failing, 374; outdoors, 329
 Myosotis dissitiflora, 455

NARCISSI, CULTURE IN JER-

sey, 108; pallidus praeox, 135, 248; Mr. Burbridge's lecture on, 260; classification, 262; albus Milneri and J.G. Baker, 284; Queen Sophia, James Dickson, and Queen of England, 290; incomparabilis James Dickson, 299, 345, 365; Tazetta floribundus, 329; abnormal forms of, 362; revised nomenclature of, 366; abscessus (N. untricus), 389; double, 446
 Nectarine leaves skeletonised, 394
 Nepenthes, culture of, 163; soil for, 193; liquid manure for, 263
 Newcastle Show, 348
 Nightingales in March, 279
 Notts Horticultural and Botanical Society, 109, 383
 Nursery, Mr. B. S. Williams', 348
 Nuts for thin soil, 114
 Nymphæas at Oxford, 244

OAKS, ENGLISH GIANT, 359
 Odontoglossum Hubyannum

ODONTOGLOSSUMS—continued
 30; Pollettianum, 135, 183; Oerstedti, macropilum, 249; erisipum guttatum and Shuttleworthi, 290; Pescatorei, large specimen, 300; cinnamomeum and vexillarium splendens, 326; in German moss, 400; vexillarium, 509
 Oncidium Jonesianum and anthocrene, 135; cucullatum giganteum, 290; leucochilum, 349; erisipum, 461
 Onions, notes on varieties, 105; transplanting & the maggot, 317; thinned and not thinned, 338; The Queen, 463; maggot, preventing, 481

 Oranges for winter gardens, 64; history of in Australia, 310
 Orchids at Newbattle, 6; out of doors, 30; prices of, 63; culture of, 72; sale and prices of, 82; for cool house, 95; culture of, 136; material for potting, 142; sales of, 165; notes on, at Mount View, Odontoglossum Roezii, Phaius grandifolius, 174; extended culture of, at Fernside, 181; at Oldfield and Sudbury House, 182; present and past methods of culture, watering, liquid manure for, 204; shading, Thunias, 222; Blettas, Phaius grandiflorus, Disa grandiflora, sale and prices, 223; Odontoglossum Pescatorei Veitchianum, 227; notes on, 249; details of potting, 264; cutting down Dendrobiums, 267; Odontoglossum Edwardi, 268; at Westbrook, 271; notes on, 280; watering, shading, and ventilating houses for, 286; fumigating, at Fernfield, Bridge or Allan, sale of, 300; sale and prices of, 325; at Pentland House, 326; notes on, 339; at Holway, 348; at Woolton Wood, 364; at Westbrook, 366; at Regent's Park, 400; Mr. Bull's exhibition of, 402; Mr. Smee's, 424; at Messrs. Veitch's, 442; Mr. Peacock's exhibition, 460; at Manchester, 470; at Regent's Park, 509; naming, 510
 Orthosiphon stamineus, 227
 Oxlips, seedling, 307

P. EONIES, 423

Palm house, new at Glasnevin, 6
 Panax Schinuseng and quinquefolia, 39
 Panicleum variegatum culture, 384
 Pansies, liquid manure for, 374; Fancy, 507
 Pansy Society, Scottish, 515
 Paraffin and fruit trees, 44, 88
 Parrotia persica, 135
 Parsley, culture of, 135, 214
 Parsnip, history of, 281
 Passiflora edulis, 154; propagation of, 374
 Peaches—at Christmas, 26; forcing and management, 52; at Wilton, 88; trees casting buds, 91; forcing, 94; house at Wilton, 27; trees casting buds, 71, 113, 131; treatment of, 133; trees at Wilton, 172; extension & restriction, 189; buds not swelling, 198; forcing, 196, 332; weevil, 314; treatment of, 372, 431; not stoning, 456; leaves blistered, 475; thinning growths of, 497; in pots, 481; forcing, 518; failing, 520
 Peak district route, 470
 Pear, Josephine de Malines, 29, 65, 79; insect enemies of, 424
 Peas—in pots, 16; growing in pots, 25; culture, 36, 51; growing early, 61; for small gardens, 74; notes on varieties, 104; for exhibition, 118; early, 162; in pots, 300
 Pelargonium Society, termination of, 26; culture of Show and Fancy, 151; good semi-double, 294; culture and varieties of decorative, 321; raisers of old Zonais, 334; for autumn, 394; double for winter and spring, 397; Chelsea Gem, 487; prolific, 520
 Pelecyphora aselliformis, 189
 Pellaea ornithopus, P. brachyptera, 103
 Pentstemons, notes on the species of, 302
 Peppermint oil, 466
 Petroleum, mixing with Gishurst, 124; for insects, 142; and its uses, 319
 Pettigrew, death of Mr., 235
 Phacelia campanularia, 69
 Phaius irroratus purpureus, 290; grandifolius, culture of, 372, 400
 Phalanopsis, culture of, 3; Schilleriana, 204, 300
 Philippine Islands, flora of, 418
 Phloxes in pots, 253

Phylloxera in Victoria, 30; experiments in destroying, 35; importation of, 107
 Pine Apple Nursery, 173
 Pinguicula caudata, 345
 Pine Apples, culture of, 473, 390
 Plantains, destroying on lawns, 333
 Plants, propagating hard-wooded, 7; protecting from frost, 47; select hardy, 55; forcing, 66; correct name and synonyms of, 84; hardy in flower, 107, 114, 148; how they obtain food, 149; hardy and their synonyms, 152; in bedrooms, 158; from seed for cut flowers, 221; synonyms, 186; new, at Regent's Park, 265; for walls, 311; for viney wall, 314; names of hardy, 350, 364; hot water for, 434; cleaning, 451; specimens at Wood Lawn, 470; growing in moss, 490

PLANTS CERTIFICATED—

Acer japonicum aureum, polymorphum septemlobum, elegans purpureum, 389; Adiantum rhodophyllum, 249; A. strictum, 25, 290; Angraecum fastuosum, 326; Amaryllides General Graham, Ne Plus Ultra, 214; Madonna, 265; Col. Burnaby, Mrs. Shirley Hibberd, Sir Redvers Buller, 249; Virgo, Zitella, 290; Asplenium horridum, 389; Auriculas Douglas's Conservative, Douglas's Mrs. Moore, Mungo, McGeorge, 83, 290; Sir W. THE CHAPLAIN'S NEW YEAR'S ADVICE TO YOUNG GARDENERS.

IF that excellently written and evidently well-thought-over article by "A Working Gardener" in our number for December 13th touched the feelings of "H. Notts," and set him thinking—and I do not wonder it did—so also did the latter's paper, which he entitled "The Journal of Horticulture," touch my feelings and set me thinking. I like now and then, and at this season particularly, to see such good advice in print—plain, practical, and, perhaps some may say old-fashioned advice, and none the worse to my mind for having an old-fashioned flavour in it. I, indeed, cannot claim to have known *The Cottage Gardener* and our Journal for thirty years, but the "Wiltshire Rector" in this periodical comes of age this year, for it is twenty-one years since he wrote his first article and sent it off wondering if it would be printed. After twenty-one years as "W. R." here (I dare not say how many more according to the family bible in the old home in Cambridgeshire) I think I may give advice to young gardeners. As we get older we are apt, I know, to become, according to Juvenal, "praisers of the days past," and must guard against being unduly so; still, it is right to regard past as well as present.

I said recently to a mechanic, "I hope your boy takes to your business." His reply was, "I have not much to complain of, but I wish he would work at little things of an evening by himself, as I used to do, and so try and improve himself; but then young people now-a-days are so much taken up with 'wonderments'—i.e., the Wiltshire for "amusements." And that father exactly hit the blot of the present age among young people. It is the ceaseless round of "wonderments," or what the very old country people in Wilts call "onderments," that take up the time over-much of youths and maidens.

Who will say that dessert is bad in itself, especially the fruit part of it? but if the dessert is eaten and not the wholesome dinner, then the dessert would do harm. So circuses, concerts, all sorts of evening amusements, now so very plentiful, are in themselves harmless, but if too much indulged in a lightness of mind comes on, and a disinclination for useful hand work or head work is sure to come on too. Perhaps the old days had too few amusements, and the world we were boys in was a trifle dull, but what grand men came out then! What reading of an evening! what knowledge was acquired! and afterwards, because of that reading, and because of that knowledge gained, how the young men rose to places of trust and good income!

Then, young men, remember the contest and the struggle of life is now keener and harder. You can't win the prizes of life unless you are much better men than the mass of men in your calling. Says Shakespeare, "If you give way or hedge aside from the direct forthright, like an entered tide, they all rush by and leave you hindmost."

Believe me, too much amusement is a great evil of these

days—it is like eating more cheese than bread, and ruins the mental appetite. The very flood of books and periodicals, novels especially, is apt to be injurious, with many books people get to skipping instead of reading, and mere looking at books in a careless easy-going fashion does no manner of good. In old days there was a saying, "Ah! he's a man of one book," meaning that he had mastered that one and knew it thoroughly.

Now young gardeners, you readers of this journal, and to whom I write, my advice is this: Take a copy yourself, exercise self-denial, and make it your own for ever by buying it. Then master each week's number before the next comes in, or else you get "mixed up" with the numbers. Pencil-mark any article you judge most useful to yourself. Then further, loose numbers are easily lost and not easy to refer to, so exercise another piece of self-denial—buy a half yearly cover, and for a few pence a bookbinder will make your half year's numbers into a book. Mark the table of contents; note on the fly leaves, "This vol. contains so and so, pp. so and so." All this I do and have done for years, and my old volumes are dear friends whom I often consult. I say to myself, "I fancy dear old Robert Fish (bless his kindly and godly memory) wrote something about this subject," and I turn to it. I know my advice is good, I know it from experience. Young men, young gardeners, rise superior to these injuring amusements and these desultory habits of reading, and grasp and hold tight your knowledge, gained by devoting evening hours to study. Secure as you feel the need of them scientific works which refer to your business. Some of you may presently find some bit of experience worth recording; if so, send it to 171, Fleet Street, and it, if useful, will be welcomed there.

Of besetting sins I need not speak, a little voice within will tell you yours. Flee from them as for your very life. I am sure healthy young men need no beer, and that saved, how many books you will be able to buy! Then, I would say, do not be discouraged by not being able to grasp the thoughts of others readily. This will come if you read slowly and give your mind to it. A blacksmith's arm was not overstrong at first, but by using it hard on the anvil it became so. So a man's mind becomes stronger by use. Read and think over that "Word to Young Gardeners," by "A Working Gardener," and equally carefully read "H., Notts" last week's advice to you. Take a manly stand against self-indulgence, and you will gain self-respect, and a man who respects himself will respect others.

Yet another word—cultivate good manners. I sometimes think we are in a sort of transition state, the old respect, some people might call it subservience, of the lower to the higher being gone. A sort of over-independent conceited tone is adopted by the young men; but this is not good manners, and it is a matter of good manners and nothing else. Cultivate then, I say, good manners to all. I hate supple-subservency, but a kindly greeting from a young man's open honest face I dearly love.

Such, then, is the advice which in all good faith I give you young men this new year. Follow it, and I feel sure you will be the better for it. Follow it continuously, and perhaps some here and there in old England and her colonies may in future years date their more steady application to their calling to this year 1884. Generation after generation pass on and away—some in each achieve success; you may not be able all of you to do this, but so act as to deserve success.

I have said I come of age in the Journal this year; for it is just twenty-one years since Mr. Johnson dubbed me his, and its, Chaplain. I was very glad to see a kindly reference to Mr. Johnson by "H., Notts." All older readers will be glad to hear that, though over fourscore, he still enjoys life in his pretty country home. Well, he dubbed me Chaplain, and in that character I have each year given words of advice, a Christmas or a New Year's homily, to our readers. I

hope useful advice. One thing I can claim, it has been advice well meant; and never more well meant than at this time, when I advise young gardeners to spend well their spare time—spend it, not waste it. With these words I wish you all a Happy New Year.—WILTSHIRE RECTOR.

BEGONIA HYBRIDISING.

PERHAPS in the whole history of horticulture we have not a more striking instance of what can be accomplished by careful hybridisation and skilful cultivation, when brought to bear upon a particular race of plants, than is presented in the case of that section of the Begonia family known as the tuberous-rooted. Not only has success been both brilliant and, in a manner, complete, but it has been attained in a marvellously short time when compared with the results of similar work on other plants, the whole work of improvement having been accomplished in about a dozen years; indeed we might almost say it has been done in half that time, for it is only during the last six years that the work of improving the habit and flowers of Tuberous Begonias has been entered upon on anything like an extensive scale. The few hybrids we possessed previous to that period were valued only because of their possessing the combined characters of two distinct species, and were raised most likely because of the interest that is usually attached to hybrids, and not with the view of their proving stepping-stones towards an improved race of garden plants. No doubt these species of Begonia proved much more pliant in the hands of the hybridist, and more prone to cross and recross with each other than is usually the case; but whatever may be the truth on this point, the fact remains that in a wondrously short time horticultural skill has developed from three or four species of Begonia a race of garden plants which, for horticultural purposes, rank among the very best of decorative utility both for the indoor and outdoor gardens.

The history of the Tuberous Begonias bears some analogy to that of the Pelargonium, out of the original species of which the Pelargoniums of to-day have been obtained by means of hybridisation. In the Pelargonium we have a strong line of demarcation between the race known as Show, French, Fancy, &c., and those generally known as Geraniums, and, so far as is known, this line has never been broken by crossing the races one with the other. Out of the crude material our grandfathers possessed in the species of Cape Pelargonium these two distinct races of plants were started, which have since then continued improving in the hands of skilled cultivators until we have now hundreds of varieties of both kinds, and Pelargoniums are absolutely indispensable in gardens.

Whether results similar to those obtained in the case of the Pelargoniums would be obtained with other plants depends largely on the capabilities of such. It is easy to point to cases where failure has been the result of attempts at improvement by means of hybridising. In the case of the Begonia, however, success with one section of the genus points to the probability of equal success with the other section—namely, the shrubby species, if the same skill and care were brought to bear upon them as were devoted to the improvement of the tuberous-rooted kinds. The riches of the shrubby species of Begonia, whether judged from their bright-coloured, large, sweet-scented, or curious flowers, or their erect or trailing, compact, or shrubby habit, or from their great diversity in form and colour of leaf, point to a field in which a full harvest would surely reward the hybridiser's pains. In their free-flowering, free-seeding nature, in the monœcious arrangement of their floral organs, these plants are possessed of just those characters that should make the work of hybridisation easy and full of good results. Whatever attempts have been made at an improvement of the shrubby species have hitherto been limited to efforts at crossing them with the tuberous-rooted kinds, and the result has always been failure. Whether success in this particular direction is capable of attainment we cannot as yet say. So far absolutely nothing has been accomplished, but it would appear that the shrubby species have among themselves all those characters which, if properly worked upon, would yield surprising results.

Although there appears to be some physiological difference between the shrubby species of Begonia and the South American tuberous-rooted kinds which prevents their intercrossing, we have several species the characters of which seem to be intermediate—these are *B. caffra*, *B. natalensis*, and *B. Richardsiana* from South Africa, *B. gracilis*, *B. Martiana*, and *B. cucullata* from South America, and one or two Indian species. In these we have the large tuber and succulent annual growth which are

characteristic of the popular tuberous Begonias, and the shrubby habit and floral characters of many of the shrubby section. It may therefore be said that naturally these intermediate species are the connecting links which unite the two distinct sections. Here we have the key to the road to success in bringing the tuberous and shrubby Begonias together by means of hybridisation, and it may be worth the while of those who are anxious to raise plants that shall possess the habit of the shrubby species and the large richly coloured flowers of the tuberous ones, to commence by operating upon the intermediate species above mentioned.

In the shrubby species of Begonia there is, as already noticed, a wide range of variation both as regards floral characters and habit. In their time of flowering, too, we have a range extending over the whole year, though the bulk of them flower in winter, which should place them in a foremost place for horticultural purposes. Many of them, such as *B. fuchsioides*, *B. nitida*, *B. suaveolens*, and the pretty *B. socotrana*, are already well known and cultivated as winter-blooming plants. In addition to these we have several hybrids raised from different shrubby species which are useful in winter—these are *B. Saundersii*, *B. Knowsleyana*, *B. weltoniensis*, *B. Ingramii*, and *B. ascotensis*. With the exception of *B. weltoniensis* the whole of these bear a close resemblance to each other. When the large leaves and tall-growing species, and those with flowers borne on long erect stalks and in large clusters, are better known and have been improved by skilful hybridisation, we shall have a wealth of fine-flowered, noble-foliaged plants of first-rate value for garden purposes.

Perhaps the only establishment where the less known species of Begonia are to be seen is Kew. There over a hundred species of the shrubby section are grown, and in looking over the collection just before Christmas we saw some thirty or forty species either in flower or in bud. Of these the most noteworthy were *B. socotrana*, whose pretty deep rose flowers are useful for cut-flower purposes, as they last for several days in water; *B. malabarica*, with large bunches of pale pink flowers; *B. xanthina*, with tall-stalked panicles of yellow flowers; *B. incarnata*, a large-leaved species, of which the variety known as *purpurea* is a handsome foliage plant; *B. heracleifolia* and *B. jatrophaefolia*. The tiny species, perhaps the smallest of all the Begonias—viz., *B. prismatocarpa*, was represented by a pan of the healthiest of plants; and its small dipetalous yellow and red flowers, peeping up from among the curiously bi-lobed dark green foliage, was quite a picture. This species never grows more than 2 inches high.—W.

CLEANSING VINES INFECTED WITH MEALY BUG.

FOR the next two months the cleaning of vineries and preparing the Vines for next year's crop will be going on. I pity anyone who has charge of Vines infested with mealy bug, for it was truly said by one of our leading gardeners a few years ago—"Those who have a mealy bug on their Vines may consider it as bad as the phylloxera." I consider it much worse, for in the case of mealy bug the gardener year after year battles with his grievance, giving the Vines their yearly dressing thinking it will be the last required for eradicating the pest; but when the thinning time comes round he finds to his horror that he has been disappointed, as he has found some on one of the bunches. Then there is nothing for it with some but the water engine—a splendid method for increasing the bug besides disfiguring the crop. Taking them out of the bunches with a small brush is another expensive method, the crop of Grapes often not worth the labour to keep the bunches fit for use.

Since Mr. Pettigrew, the able gardener at Cardiff Castle, explained in the pages of the *Journal of Horticulture* the way we got rid of the bug in our vineries I have had many letters from gardeners asking for more information on the subject, and the following successful method in my case may be relied upon.

Presuming there are many gardens with a range of glass composed mostly of vineries with an entrance at each end, they are advised to proceed as follows. Our plan is to commence cleaning the middle house, taking all bedding plants out, if any, and leaving nothing but the Vines to be dealt with; then cover all the border to the depth of 9 inches with long litter from the stables—this saves the soil from being trampled on too much, and catches all insects that may be washed off the Vines or the house. The Vines are next taken down, pruned, and laid along the front of the house; all the loose whitewash is then scraped off the back wall, and nothing is speedier for this work than a Dutch hoe. When the wall is finished and all the dirt settled we give the house a thorough washing down with the water engine, mixing the water with paraffin oil, a little stronger

than it is generally recommended. During the time that the engine is going we cover the Vines with mats; we then wash the Vines with soap and water before taking off any of the bark—this damps the webs that surround the bug, and prevents it blowing about and settling on any part of the house that has been cleaned. After the Vines have been washed, and before they are dry, any loose bark can be taken off and the rods again washed with soap and water; they are then ready for the effectual cure.

To a mixture of clay and water about the thickness of cream one-third of coal tar is added, stirring till properly mixed, and one man keeps stirring the mixture during the time that another is painting the Vine rods. An ordinary painter's brush is used, and instead of keeping the mixture off the eyes of the Vines, as lately advised, rub it well in.

When the Vines are completed the woodwork of the vinery will be dry. This and the wires are then painted. We prefer to do this inside painting ourselves, taking care to fill up every crevice with pure paraffin, then with putty. When the painting is finished the Vines are tied in their places, the long litter is removed, and any loose soil on the border as well; but if the soil is very dry we sprinkle it with water to keep down the dust. Then for a finish the back wall is whitewashed, the hot-water pipes painted, and the border top-dressed. The next vinery can be proceeded with in the same manner as already stated, using fresh litter for the border, and if the plants have to be returned to the vinery that has been cleaned great care should be taken to brush off all soil of the bottom of the boxes or pots.

The advantage gained by commencing in the middle of the range is that we can work to the ends, which prevents carrying rubbish through the houses that have been cleaned. Anyone who has to deal with mealy bug on Vines is advised to give the above plan a trial.—DAVID MURRAY, *Culzean Gardens, Maybole.*

CULTURE OF PHALÆNOPSIS.

WHERE the requisite heat and moisture can be afforded it is questionable if any Orchids are more worthy of cultivation than the above. They are now within the reach of all, as the price asked for them is comparatively low, yet they have not found their way into gardens generally as other Orchids have. This may be accounted for because the idea has become established that these plants are difficult to cultivate, and certainly when seriously checked no Orchids will decline more rapidly in health and vigour; but if carefully attended to their cultivation is rendered easy and success is certain.

An Orchid house is not really necessary for the successful cultivation of Phalænopses; on the contrary, they will thrive in any ordinary growing or suitable temperature. I have frequently seen them in a mixed collection doing much better than in the Orchid house. In the majority of gardens there is a stove, and therefore the system of cultivation that will suit Phalænopses in these structures will be detailed.

The only imported plants of Phalænopsis I have had were established on pieces of bark when they arrived. They were given a moderate degree of heat and moisture and heavily shaded until they commenced growing, which they did in a very short time. Small established plants are very much the best to commence with. No time is better than the present to obtain plants, but care must be taken that they are dispatched during mild weather, and the train by which they are sent should be met, if possible, to prevent the package containing them remaining long in the cold. Their growth is generally completed now and the plants are not making new roots, consequently are less liable to be checked than would be the case if they were in active growth. They are generally sent out in small pans, in which they should be allowed to remain after placing them in the stove, where the temperature at night is about 60°, until February. They should be kept in a moderately moist atmosphere, and the compost never be allowed to become dry. Place them over some moisture-holding material near to the glass as possible. I do not suspend these little pans from the roof because they dry too rapidly. A light position, and plenty of moisture in the atmosphere and at their roots, are required until their roots commence advancing.

Phalænopses are very free-flowering, and the majority will throw up flower spikes, which should be removed from small plants directly they are seen. We are all anxious to see the flowers of new arrivals, but in this case I strongly advise making a sacrifice rather than injure, or at least impede, the progress of the plants by allowing them to flower. If the flower spikes are removed as soon as they appear the plants will commence forming roots by February, and should at once be placed in baskets. The most suitable size is 7 inches square and about 3 inches deep, made of either white or red pine; in fact, any soft wood I prefer to those made of teak. The roots do not cling to the teak with the same freedom as they do to red pine. These decay

much sooner than the baskets made of teak; and even this I consider an advantage, for the wood when decayed is easier removed from amongst their roots if they require larger baskets. If teak is used no attempt must be made to take them out of the basket, but when larger are required the one in which they are growing must be placed inside that of a larger size. A few large crocks should be placed at the base of the baskets and then filled level full with lumps of charcoal, and over these a good layer of living sphagnum moss. This should be well raised in the centre, so that the plant when ready can be placed on the surface. The moss used must be picked clean and placed the day before it is required in the house. The young plants can be turned out of their pans and all the old compost removed, and their roots washed clean in tepid water. Any roots that are dead or have been injured in transit should be removed with a sharp knife. After this place the plants on the raised moss in the baskets, and work some of the same material carefully amongst their roots and above where the new roots are springing from the collar; a little moss should also be placed between the pieces of wood that form the basket and next the charcoal. I may here add we use nothing but living sphagnum moss as a medium for the roots of these plants, and this with established plants is picked out annually and fresh supplied, the small particles being thoroughly washed from amongst the roots and charcoal by pouring tepid water out of a small watering can into the baskets.

After placing the plants in baskets the position in which they should be suspended is the next consideration. Our plants are grown in the stove, which runs nearly north and south, the door being at the former end and a brick end at the latter end, which is covered with Ferns, Lycopods, &c. The plants are suspended under the last light (south end) on the east side of the house. The condition of our plants proves that they enjoy the position accorded them, and when they are once found to grow luxuriantly in any position do not shift them, or they may gradually decline in vigour.

Watering and syringing are of particular importance in the successful cultivation of these plants. Directly they are placed in their baskets a good soaking of warm water should be given them, and afterwards spray them with the syringe twice daily. Encourage the moss to grow from the time it is first placed in the baskets, and after it is started give abundance of water. If the atmosphere is moderately moist and the moss growing luxuriantly we find the plants receive just the treatment they require as regards water and moisture. When the season has fairly advanced I lightly syringe the plants many times during the day when bright and warm—in fact, never allow the wood of the baskets to become dry. During the growing season the baskets and moss should be saturated with water. As the autumn advances I syringe the plants less, but never fail to do it once daily unless the weather proves very sunless or wet. Even during the winter I give sufficient water to keep the moss alive and healthy.

Shading is of great importance and cannot be dispensed with. They cannot bear strong sun, and if allowed to strike directly upon them injurious results will follow; on the contrary, shading should not be carried to the opposite extreme at the expense of light. Fixed shading should not be employed, and only such that will break the direct rays of the sun. The position our plants occupy compels particular attention in the morning, and often it is necessary to shade them by 7 A.M., especially in the early season, until the Allamandas spread over the roof. Fortunately the morning sun only affects the plants, that from the west being shaded from them by means of blinds during the afternoon; and the blinds on the side where they are suspended can be drawn up early in the day, and thus the plants receive abundance of light to solidify their growth. Light is important, for if a soft growth is encouraged the plants fail to pass the winter in such good condition as they will when the foliage made is thin and leathery.

Air is admitted freely on all favourable occasions during the summer. We commence early in the morning as soon as the temperature is rising by admitting it at the base, the ventilators being formed in the brickwork below the side stages and opposite the hot-water pipes, and then from the top if the temperature continues rising. Early in the spring when the air is cold the blinds are preferred to admitting cold currents of air, and seldom during the winter and spring are the top ventilators opened. I am no advocate for a close confined atmosphere, and prefer the admission of air daily, if only for half an hour, if it can be given with safety.

If the plants become unhealthy the best plan to recruit them is to turn them out of their baskets and remove all dead and decaying roots, and wash those that are alive. They should then be secured to a piece of wood or bark with the smallest portion of moss, and again suspended until they commence rooting afresh, which they often will do in a very short time if they have not been allowed to decline too far.

The night temperature of the house in which our Phalænopses are

grown ranges about 60° during the winter, with a rise from fire heat of 5° by day; summer temperature, night 70° to 75°, and by sun heat 85°, and often run up to 90° and 95° when the house is closed in the afternoon. We draw no hard-and-fast lines in the regulation of temperatures, and are guided entirely by external conditions.

Amongst insects thrips prove the greatest enemy to these plants, as they soon injure and disfigure the foliage. If watered and syringed as described these insects will not trouble the plants during the summer; but if they appear in winter sponge the foliage frequently with a little weak tobacco water.—W. BARDNEY.

CHOU DE BURGHLEY.

I WAS surprised on opening the Journal of last week to see the letter of "A Working Man" condemning the excellent vegetable Chou de Burghley. I have grown a bed of them, and in no way do I regret the experiment. Mine have not made any very white hearts, but they have been very good when cooked. They have had some frequently in the kitchen here, and the cook, who by-the-by, is good at cooking vegetables, thinks there can be but one opinion about it—that it is an excellent vegetable. My wife has also cooked some, and she tells me it takes but very little longer than ordinary Cabbage to boil, and is always very pleased when I bring any in for dinner.

I quite agree with your correspondent, Mr. T. W. Sanders, in his remarks about Peas, as I find Ne Plus Ultra to be the best late Pea.—A SUSSEX GARDENER.

THE merits of the above having been much discussed in the Journal lately I cannot refrain from giving my experience, especially after what your correspondent, "A Working Man," says on page 531. My experience is quite the reverse of "A Working Man's." Having heard so much of its good qualities I decided to give it a trial. The seed was sown the first week in April. When the plants were large enough, and as our garden is small, to make the most of it they were planted between rows of Peas. With no better treatment than this they did remarkably well. We commenced cutting early in September. But before introducing them to the cook I tried them myself, and must say candidly that they proved delicious, and, to use Mr. G. Abbey's words, as "tender as a chicken." In fact, all that Mr. Abbey says on page 511 respecting them I can endorse, as his experience exactly coincides with mine. Since introducing them to the cook they have been well patronised, and not through necessity, as we have now, and have had all along, a good supply of Cabbages. As regards the time required to boil them as "tender as chickens" we find half an hour ample. I may add, however, that a small lump of soda is placed in the couter in which they are to be boiled.

Thus having proved to my satisfaction its great superiority to Cabbage and kindred vegetables in every respect, I shall take care to have a good supply in the coming season.—J. RICHARDSON.

"A WORKING MAN" on page 531 gives evidence of the 'cuteness resulting from an education above the ordinary character, and upon that I beg to compliment him; at the same time I may remind him that it is only misapplied when employed to criticise others not so favourably circumstanced in that particular, or to call in question their veracity. Does "A Working Man" think anyone can spend thirty-six years in a garden and not know the difference between a Cabbage and Chou de Burghley? I do not suppose "A Working Man" will care to know that I am not a "cook," but I have the authority of a good one for saying that it takes no more time to boil Chou de Burghley than Cabbage, Savoy, &c. But as "A Working Man" is so fastidious I may tell him that I boiled some Chou de Burghley as "tender as a chicken" in thirty minutes, the time being reckoned from the boiling. The flavour is "in" the vegetable, and only needs to pass a palate unimpaired by coarser vegetables to be recognised as distinctly marked. Lastly, I may inform "A Working Man" that I have been acquainted with Chou de Burghley since 1878, when it was awarded a first-class certificate by the Royal Horticultural Society, and there surely has been ample opportunities of testing its hardness since; but it is only this season I gave it a fuller trial to test its merits, and discovered it excellent, which is more than can be said for many "bastard" Broccoli that have been made to stand for the legitimate article. It is a mistake to presume that Chou de Burghley cannot be taken after Potatoes, as both our batches followed Myatt's or Veitch's Ashleaf. It may be true that it takes up more room than Cabbage of the Little Pixie type, yet ours are only planted the ordinary Cabbage (not Pixie) distance, and one head is worth half a dozen Little Pixies in both bulk and quality. The one is coarse (as I maintain all winter Cabbages are), and the other delicate and delicious, without a trace of "Broccoli leaves" flavour, or Broccoli either.—G. ABBEY.

FRAGRANT ROSES.

THE following Roses may be added to your list of Hybrid Perpetuals on page 540 as well scented; some of them are very fragrant. I have not included sorts which have been withdrawn from the sale catalogues. There are several very richly scented Roses which might be added to the list, but which, though occasionally classed as Hybrid Perpetuals, are commonly ranged under some other title, as Miss Ingram, or as H. B.'s, Acidalie, Sir Joseph Paxton, and others. An objection may be made

to a few in my list as not well scented, and I may have erred in a few instances where I have not the variety in my gardens. I wish some competent person would perfect a list of all the well-scented Roses in cultivation.

It has given me much pleasure to read the arguments of your correspondents in favour of propagating Roses on their own roots instead of upon foreign stocks. There is not a point in the observations I sent to you that has not had the countenance of experienced rosarians.—W. SIMONS.

ASTROCARYUM MEXICANUM.

THE genus *Astrocaryum* belongs to the *Cocoeæ* section of the order *Palmaceæ*. It is composed of a few handsome species, and amongst them *A. mexicanum*, a representation of which is given in fig. 1, is by no means the least elegant.

The species are all more or less armed with long, sharp, and formidable black spines. The genus is distinguished by its unisexual flowers, which, however, are not produced on separate plants, but really upon the same spike. The spikes are simply branched, and the female flowers are confined to the lower portion and the males to the upper, which would appear to be a wise arrangement of Nature to insure the fertilisation of the flowers, for with their positions reversed impregnation would be extremely problematical. The fruits are oval and single-seeded. In their natural habitats the plants affect the banks of streams and large rivers, and I believe they are seldom found at any great distance from water which is the general rule with Palms armed with spines. *Astrocaryums* are slender-stemmed plants, carrying extremely handsome heads of broadly pinnate leaves, which in *A. mexicanum* are dark green on the upper side and pure white beneath. This species is extremely ornamental in a collection of tropical plants, and is also one of the best for exhibition, either in a collection of Palms or mixed stove and greenhouse plants; but it will never become an amateur's plant, or a plant for the decoration of apartments, for the simple reason that it will not long retain its beauty out of the temperature of the stove.

The soil best adapted for *Astrocaryums* is a mixture of loam and vegetable mould in the proportion of two parts of the former to one of the latter, adding sufficient sharp river sand to make the whole feel

gritty in the hand. The young plants should be potted firmly; and liberally supplied with water both winter and summer; indeed, in summer it will be highly beneficial to place the pot or tub in a large pan of water.

A figure of the fruit of this plant was given in the Journal, page 553, vol. v.—E. C.

PAST v. PRESENT WRITERS—OLD AND YOUNG GARDENERS.

WHAT is the matter with "H., Notts?" Is his communication on page 544 last week a burlesque, or was it penned in "sober seriousness?" Conscious, no doubt, of inherent strength, the Editor did not "stop" his hypochondriacal correspondent, preferring apparently to leave him to the Philistines.

The "modern scribes" whom "H., Notts," is so much concerned about are no doubt quite able to take care of themselves; but does he not perceive that they cannot oppose his dogma without laying themselves open to a charge of egotism? Not a few men of undoubted ability hesitate to proclaim their own "skill and capacity." They succeed, however, in maintaining their own credit by the excellence of their work, and endeavour to be useful to others by communicating knowledge born of experience.

Why, as a disciple of the honoured men who have gone before, does not your clever correspondent follow their example? It is clear he has the pen of a ready writer, and if he possesses in an equal degree sound and practical knowledge on gardening matters, as presumably he does, would it not be more consistent to endeavour to make some return by enriching the pages of a journal which he admits has done so much for him, than to spend his time in demonstrating the truism that every generation does not produce a Macaulay, Scott, or Shakespeare?

Your correspondent's strictures on young gardeners are far too sweeping to be reliable. With as much accuracy he might represent that *all* the gardeners of the past were as good and able as the few he quotes, and himself, as that *all* the young men of the present are as his peculiar fancy has painted them. Extreme criticism, however, seldom does harm, because—it is extreme.

Some thoroughly good practical articles like those of old will now be expected from "H., Notts," by—A PHILISTINE.

HOWEVER good the object may be of many of those who write for the advice of young gardeners, it is to be feared that the amount of good done is not at all proportionate to the quality and quantity of the advice tendered. Gratuitous advice is not welcomed by those it is intended for. It is well meant, none of us doubt that, and we listen respectfully to what is said for our special edification, admire or laugh at it, and very often forget it. Speaking for that portion of the readers of the *Journal of Horticulture* and other garden periodicals who do not read "skimingly and slightly," as "H." asserts the larger portion of young gardeners do, it would be far more edifying to them if the matter submitted for their instruction savoured less of the lecturing style and more of good practical information on subjects horticultural. If we are not as good as our grandfathers were when young, it cannot be for lack of advice; but it is well to remember that Beatrice said she could easier advise twenty than be one of the twenty to follow her own instruction—a common failing among our species.

"H." leads us to believe that he has long passed through the snares and pitfalls which beset the path of youth, and that he has passed through unscathed. We heartily congratulate him, as also we do on his having acquired ability and skill sufficient for his present position, which we trust is a good one; and we shall not attempt to rob him of the satisfaction he derives from the result of his comparison of to-day's young men with those of a past age when garden literature and gardeners were superior to what they are now. We do not admit, and will not deny, the accuracy of his opinion. Nothing to our advantage would accrue from the discussion of such a dictum. His sweeping accusations against the present generation of young gardeners, however, cannot be allowed to pass with impunity. He says, "I know quite well that the old plodding spirit is fast dying out of our young men," by which he must mean that there is a want of perseverance and energy observable in their work. How does "H." know that? Such an accusation ought not to be made unless it can be proved, and it appears to us that to "know" that it is so is rather more than falls within the ken of any man. Not a single fact is adduced in support of such a charge, and it seems to us there is an abundance of facts which lead to a very different conclusion. The high tone of garden literature generally and the large demand there is for such, the steady rapid advance in all branches of horticulture made during the last decade, the interest taken in the scientific branches of gardening art, are due at least as much to

the younger as to the older votaries of horticulture. Skill and intelligence on the part of the subordinate play a large part in the successes of any garden. If I might be allowed to make a comparison between the young and old gardeners I should point to the exhibition tent, where the young meet in competition with the veterans of horticulture, and are not always second. I do not mean to assert the superiority of the younger gardeners, but I do most unhesitatingly aver that we have abundance of proofs that horticulture will not be allowed to fall from its present high position by those who are to continue its work. If "H." has the misfortune to know only the dark-coloured sheep of the flock, let me assure him that there are plenty of white ones also.

With regard to education, we all know that success in any proper calling is through the school-book. But the growth of intellect depends on much more than a study of Lindley Murray and Colenso. To exclude all subjects from the studies of young men but those bearing directly on their vocation is as fatal in horticulture as it is in every other calling. A good foundation of general knowledge is the keystone to the study of special subjects. The mental powers must be first of all cultivated before they are used, and the higher the cultivation is the better will be

Fig. 1.—*Astrocaryum mexicanum*.

the results. "The brain is like the hand, and grows with using." There are many things essential to the make-up of a good gardener besides a knowledge of rotation of crops. One-idea men are narrow-viewed.

What "A Working Gardener" says on the subject of pleasure is pretty much what we heard at school. Until we are old men the delights of youth have their fascination, and we are not to be deprived of them. I am afraid to think what sort of beings we should be moulded into if we followed all the advice that is given. Is there to be no pleasure for young gardeners? It has its place in every young man's existence and to ignore it shows lack of wisdom on the part of our self-appointed advisers. I enjoy my "cane and kid gloves," a dance, a song, a novel when I am tired with or do not feel inclined for harder studies, and I do not think they harm me. Life is surely something more than mere bread-winning. In conclusion I would say advice is thrown away on those who are determined to get on; and for the black sheep—well, perhaps they read it—but in the words of the proverb, "You can bring a horse to the water but you cannot make him drink."—A YOUNG GARDENER.

RELATIVE to the VEITCH MEMORIAL prizes alluded to on pages 529 and 548 of last Volume, the Trustees have decided to allot the following medals and prizes during 1884—namely, I. A Veitch memorial medal and prize of £5 for each of the following subjects: (1) The best specimen Orchid in bloom; (2) the best stove or greenhouse plant in bloom; (3) the best dish of two bunches of Grapes, one variety—these to be offered at the Dundee International Show which takes place on September 11th to 13th. II. A Veitch memorial medal and prize of £5 for (1) the best specimen Orchid in bloom; (2) the best stove or greenhouse plant in bloom—these to be offered at the Royal Botanic Society's Show on May 21st; and for (3) the best dish of three bunches of Grapes to be offered at the Royal Botanic Society's Show on June 18th. III. A Veitch memorial medal and prize of £5 were also placed at the disposal of the respective Committees of the National Auricula Society (Southern Section); of the National Carnation and Picotee Society (Southern Section); and of the Committee having charge of the National Dahlia Show. These prizes are only eligible to be competed for by amateurs and *bonâ fide* gentlemen's gardeners.

— WE learn that Messrs. Boyd & Sons of Paisley have entered into a contract with the Government to construct, for the sum of £4300, the NEW PALM HOUSE AT GLASNEVIN, which is to be 100 feet long, 80 feet wide, and 65 feet high. The new house is to be built over the old one, the latter to stand till the completion of the new and more imposing structure.

— THREE or four tubers of the NEW SPECIES OF POTATO, discovered by M. Ohrond at the mouth of the Rio de la Plata, and named after him *Solanum Ohrondi*, have been forwarded to Mr. Burbidge, of the College Botanic Garden, Dublin, from the Continent, and he will grow them in the coming year.

— A CORRESPONDENT obliges us with the following notes:—"As far as the winter has gone the weather has been extremely mild in the north, and it can hardly be imagined that Christmas is round again. When at DALHOUSIE CASTLE, N.B., the other day Mr. Johnstone, the gardener there, stated he had cut twenty-two dozens of China and Hybrid Perpetual Roses from standards and dwarf bushes growing in a rather exposed situation on December 17th, and on December 24th there were some beautiful Gloire de Dijons on the walls in the garden. The yellow Jasmine was also very beautiful. In the houses there were some fine samples of Gros Colman and Lady Downe's Grapes well finished. Dalhousie is a beautifully situated garden, and the surroundings of wood and water are charming. The Castle dates far back, and has an interesting history."

— ORCHIDS AT NEWBATTLE.—Orchids are extensively grown at Newbattle, and there are some fine specimens of many of the choicest varieties. The noble owner takes great pleasure in these interesting plants, and has had specimens of most of the varieties bloomed at Newbattle painted by a lady artist. There are a great many so depicted, and being done on a large scale and finely mounted they form a splendid collection and fill numerous large portfolios. Anyone fortunate enough to see these beautiful paintings cannot fail to be delighted.

— A VISITOR remarks that although seldom seen in ordinary gardens BROMELIADS are nevertheless well worthy of accommodation in every stove, and would well repay any extra attention by the brilliancy of their varied colours. In the stove at Kew these plants are made a speciality, which is well repaid by the constant supply of flowers. Among those in flower at present may be noted *Vriesia brachystachya*, *Æchmea cœlestis*, *Æ. calyculata*, *Lamprococcus fulgens*, *L. Weibachi*, *Pitcairnia zeæfolia*, and *Bilbergia Lietzei*, which has flowers about 2 inches long and very finely coloured.

— MR. H. LISTER, The Gardens, Easton Lodge, Dunmow, writes—"I have this season had a sport from *Chrysanthemum Empress of India*, which seems to be identical with Lord Alcester, judging by the description given. The bloom is large, well-built, and the colour is pale

yellow, somewhat like George Glenney." It is strange how on several occasions similar sports have appeared in different parts of the country about the same time.

— THE true name of a bulb that is being pretty generally distributed under the title of *Bulbocodium trigynum* is *MERENDERA CAUCASICA*. The difference between the two genera to the casual observer is hardly discernible, and consists only in the *Merendera* having the three styles free, while in *Bulbocodium* they are undivided. The above-mentioned plant, from the fact of its coming into flower at this early period in the open, and also in its floriferous character—each bulb generally producing from five to seven pure white flowers, those of the *Bulbocodium* rarely producing two—is likely when better known to be extensively cultivated. It requires similar treatment to the other members of the genus.

— AMONG the many hardy bulbs that are welcome at this season of the year *COLCHICUM LUTEUM* and *C. CROCIFLORUM* are very notable for neatness of habit and brilliancy of colour. *C. crociflorum* is a native of Turkestan, whence it was introduced two or three years ago by Dr. Regel. The name *crociflorum* was used for a variety of autumnale, and also for montanum, but the Turkestan plant is so distinct that no difficulty will be experienced in distinguishing it. The flowers are small and very neat, the inside pure creamy white, the flowers appearing before the leaves. *C. luteum* is the only species having yellow flowers, it belongs to the group inhabiting the Mediterranean. The flowers are much larger than the last, pure yellow, and a great acquisition amongst Christmas flowers. Both the above may be had in flower in December by simply protecting them with handlights in severe weather.

— "M. S." writes—"In the note of the meeting of the Society of Arts Dr. J. F. Watson does not speak very hopeful regarding the general cultivation of RHEA OR CHINA GRASS (*BOEHMERIA NIVEA*). In the neighbourhood of London, and I have no doubt farther north, this plant instead of requiring great care in cultivating as stated is quite hardy, and in ordinary soil the stems attain a good height. In a few places I have seen large patches growing quite exposed, and I was told they had not been disturbed for three or four years, and appearing stronger every year, a fact which goes a good way to prove that if there was a possibility of market growers or others being able to obtain good healthy roots we might yet be able to cultivate this valuable fibre and supply the market at a much lower price than £35 per ton. It is partial to strong soil, and ought otherwise to be fed occasionally with liquid manure. The roots should in no case be disturbed."

— A REMARKABLE instance of mimicry in plants is to be seen in the close resemblance of *SENECIO MACROGLOSSA* to the COMMON IVY; a resemblance so close, in fact, that without the flowers to guide us it would be difficult without closely scrutinising the plant to perceive any difference between them. In addition to this interesting character *S. macroglossa* possesses good horticultural qualities in the size and beauty of its flowers, which may not inaptly be compared to some of the now popular single Dahlias. They are yellow, the size of a crown piece, and are borne in considerable numbers on the points of the growing shoots. Flowering as it does in midwinter and under conditions as regards cultural management that are met with in most gardens, we are surprised that the plant is so little known.

— THE fortnightly meeting of the MANCHESTER HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY was held last week at the old Town Hall, King Street, when a very large company was present. Mr. Bruce Findlay, President, occupied the chair. Mr. W. Birkenhead read a paper on the cultivation of Ferns. He dwelt upon the natural conditions in which Ferns are met with, noticing how modest and retiring a spot many of them choose for themselves; so in our attempts to grow them a quiet and shady position will suit many which, if placed in high and airy stages, would cause many to shrivel and pine away. *Todea superba*, *Todea pellucida*, and many of the *Hymenophyllums* would come under this head, and among this class less heat was needed than hitherto many had been disposed to give. He had received letters from gentlemen in many parts of the country assuring him that though their plants had been frozen for days together, no harm whatever had resulted from such a severe ordeal. *Nothochloena*, *Cheilanthes*, and *Gymnogrammas* must have a treatment in many respects the opposite of the preceding. Light, an airy situation, and much less moisture would be required, and when successfully managed they are amongst the most beautiful of the family.

Mr. Birkenhead showed the folly of potting Ferns too firmly, preferring a rough open soil in which cinders and sand formed a not inferior part. A number of questions were asked and replied to, and some further information on the subject was imparted by the members who took part in the discussion, amongst whom were Mr. Ellis (Pendleton), Mr. Nield, Mr. T. Lunt, Mr. W. Plant, Mr. McKellar, Mr. Findlay, and the Honorary Secretary, Mr. W. Swan. It was announced that the next meeting would take place on Thursday, January 10th, 1884, when Mr. F. Robinson (Messrs. Dickson & Robinson) will read a paper on the Tulip.

— A LOVER of bulbous plants writes—"I read in the Journal recently with much pleasure that a border was being prepared at Kew for CHOICE BULBS OUT OF DOORS, and during a recent visit to that establishment I observed that it was completed and partly planted. It appears to have been done in a very thorough manner, and I shall look forward to many pleasant visits in the future, when I may expect to see some of my old favourites in flower. We are all familiar with the brilliance of Tulips, Hyacinths, Crocuses, and others that are usually employed for bedding purposes, but too few know the number of delicately beautiful plants included amongst many genera of the great families Liliaceæ and Amaryllidaceæ. Except to botanists and a few specialists hundreds of these are unknown, and it is to be hoped that this praiseworthy experiment at Kew will assist in popularising a really charming and much-neglected group of plants. Much also will undoubtedly be added to the small store of knowledge we possess concerning the cultural requirements of many of these plants, for with the exception of such experienced cultivators as Mr. Green of Pendell Court, few have had an opportunity of studying their special wants, and the recorded information available upon such matters is too often quite unreliable."

— THE third number of the "SCIENCE MONTHLY" continues its work in a satisfactory manner, and contains well-written articles upon "Earthquakes," "Lost Comets," "Some Account of New Guinea," "Lessons from Common Plants," "Extinct Volcanoes of the British Islands," and a biography of Sir William Thomson, with a portrait. The columns devoted to scientific news are filled with interesting facts, and the various other departments are also well supported.

— THE December issue of "L'ILLUSTRATION HORTICOLE" contains coloured plates of three very distinct plants. One of these is *Echeveria decora*, which is believed to be a variety of *E. metallica*, resembling that species in habit and form of the leaves, but the colouring is very different. The principal ground tint is a peculiar purplish green with irregular stripes of pinkish yellow, the stem being of a pale rosy hue. *Tapeinotes carolinæ* var. *major* is a handsome Gesneraceous plant with fine elliptical or oblanceolate leaves, deep green, with a glaucous tint on the upper surface, and rich red beneath. The flowers are produced freely from the axils of the leaves, the stalks being nearly erect, but the corollas hang downwards. They are curiously bulged at the middle, but much contracted near the mouth; the lobes are small, rounded, and pale yellow, the other portion of the flower being white. The calyx is large with ovate tapering sepals, deep green, edged and tipped with red. The species was discovered in Mexico in 1859 by Dr. Wawra, and the variety was introduced to the continent by M. de Macedo Costa of Bahia. The third plate represents *Batatus paniculata* a strong-growing and beautiful climber that is too little known in gardens. The leaves are large and deeply divided into five to seven narrow palmate segments. The flowers resemble a large *Convolvulus*, and are of a rich rosy colour, the centre and tube being deep crimson. It flowers very freely and continuously, though the blooms individually are of short duration. A fine specimen is grown in the old Lily house at Kew.

— THE *St. James's Gazette* in discussing "Neglected Vegetables," has the following with regard to the fruit of the purple Egg-plant, or AUBERGINE:—"Another most valuable plant, unknown in this country save as an ornament in the quasi-tropical gardens or in shrivelled specimens in the windows of the foreign dealers in Covent Garden Market, is that for which we have no English name—*Solanum melongena*, the purple variety of the Egg-plant, known in France as Aubergine, in Spain as Berengena, to Anglo-Indians as Brinjal (a corruption of the Spanish name), and to Turks by a name most impolite. This is one of the most precious of the great *Solanum* family, greatly esteemed all over the tropical and warm temperate world, which only needs to be better known in England to be liked as much as its first cousin, the Tomato. Supposed to have been originally introduced from

America, the use of the Brinjal has spread all over the East. Sancho Panza tells us that the Moors of his time were especially fond of it. In Spain it has always been most popular. The Brinjal in its habits is very like the Tomato, and may be grown in English gardens without any more trouble. As with the Tomato, the main secret of success is to sow the seed in a hotbed or under glass, and have the plants well forward before they are put out into the open. In an ordinary English summer the fruits ripen readily against a south wall, the plants requiring no further care than copious and constant watering. The Brinjal may be cooked in various ways—either cut in slices and fried in oil, or parboiled and then the interior taken out and fried with force-meat, or put into stews and curries. One precaution it is necessary to take, and that is to steep the fruit, after being cut in half, in water for half an hour or so. This is done to expel the poisonous element which this, like all the other members of the genus *Solanum*, contains in more or less degree."

PROPAGATING HARDWOODED PLANTS.

"A FOREMAN" (page 552) says that *Ericas*, *Epacris*, and *Azaleas* should be propagated in the spring and *Camellias* in the autumn. I would advise your correspondent to propagate *Ericas* in September, and then not in a forcing house, and when standing them in the open air not to place them behind a north wall, but in the open, so that one plant shades the other, placing a piece of board against the outside row of pots; then, with attention to stopping at the proper time and careful watering, plants may be had with a good constitution and masses of bloom by the time their blooming season arrives. I can assure "A Foreman" that those robust plants in 48's that may be seen in Covent Garden Market by thousands at this time of the year are not grown under the system he recommends. *Azaleas* and *Camellias*, I think, are best grafted. A good stock for *Azaleas* is *A. Sir Charles Napier*, but gardeners as a rule do not graft them, leaving this work to the trade.—A. YOUNG.

STORED-UP SAP IN VINES.

"It appears to me," says "Beta," "that he has avoided repeating the statement as to the exact size the shoots and leaves attain before the stored-up sap is exhausted. In his principal argument he is undoubtedly right, but in this I consider he errs, and I would advise a graceful retreat from an untenable position."

Now I cannot understand that anything has yet occurred to make my position untenable. The mere assertions of half a dozen people who have no records of experiments to support their particular views certainly will not do it. As I have said before, my theories and deductions are open to criticism and argument, but the facts of observation must be taken as absolute facts. I will re-quote the passage from "Beta's" letter, and point out where the practical facts end and where the theory commences. "The shoots are now from 3 to 7 inches long, with two to four fully expanded leaves, the largest of which measure $4\frac{1}{2}$ or 5 inches across. Here and there in a few of the older ones are patches of dark colour, a sort of bluish green, only visible at present to the practised eye which is watching for its appearance. Yesterday it was only discernible on two or three leaves, now it shows slightly on a score or more." Then comes the bit of theory, which we will leave out for the present.

If the above passage had been written last month from memory there might be grounds for suspecting I had stretched a point, but when I state that it was written word for word on the precise date I attached to it and in the house where the Vine in question was growing, and that all measurements recorded in the series of articles from which this is extracted were taken carefully and booked at once, and that in no case did I stretch a single hair's breadth, it will be owned that I have good grounds for sticking to my point. No, "Beta," I thank you for your letter and advice, but I shall not retire "gracefully;" when I do retire it will be because I am beaten, and then gracefulness will be out of the question.

I shall have more facts and figures to record which I know will not be received by everyone, and I own that some of them surprised myself, but that is no reason why I should withhold my notes. There will be ample opportunity for hundreds of persons during the next few months to test the veracity of my statements, and I can assure them that if they will take the pains to go into the matter deeply and carefully that they will find an inexhaustible fund of interest.

Now for the little bit of theory which has caused so much discussion. It is to the effect that the appearances noted above and recorded within inverted commas "indicate that the roots have commenced action, and that the leaves are no longer dependent on the stored-up food which was prepared last autumn and preserved in the stems for early use." True this is pure theory, in which, as far as I know, I am not supported to the full length by any professed physiologist; but, on the other hand has any learned physiologist made the Vine (which I hold to have an economy peculiar to itself) a special study?

The notes of observant cultivators who have recorded experiments during the discussion have partly supported my theory, and mere assertions, however numerous, without a shadow of proof to support them, carry no weight whatever.

Have none of your readers noticed the remarkable, almost magic-like change of colour which comes over the leaves of a Vine at the particular

stage referred to? I am acquainted with several persons who have watched for its appearance and could not detect it, but after it was once pointed out to them in even a single leaf they had no further difficulty. True, I cannot prove to the letter that this colouring is the result of the commencement of root-action; but as I have proved hundreds of times within the last twenty years that the colouring and root-growth commence exactly simultaneously, I may be pardoned for believing that there is some sort of connection between the two.

"Beta" proceeds: "Is he also prepared to adhere to his statement that root-action and root-extension are synonymous terms?" With the addition of the words used by me to qualify this sentence—viz., "for all practical purposes," I am prepared to adhere to it. I presume from "Beta's" very fair and sensible letter that he does not want to enter into any physiological hair-splitting on the wording of this sentence, but that he is only anxious to get at my meaning. It must be distinctly understood that mere absorption of water is not root-action, because the same thing goes on when cut flowers and cut stems of Vines are placed in water. I have, I believe, laboured as hard as anyone to show that water is continually being absorbed by plants during the winter in large quantities, and I take some credit to myself for assisting to bring the old-fashioned drying-and-resting theory and practice into disrepute, which was so common scarcely a dozen years ago. Water can, of course, be absorbed by any part of the root or any part of the stem placed in a moist medium; and if it is correct, as some authors assert, that some salts in solution are also taken up at the same time, that does not constitute root-action.

It would appear, however, from the following quotation that Dr. Masters thinks that only the *aqua pura* is so absorbed. He says in "Plant Life," page 21, "The soil, therefore, is not to be looked on as containing so much liquid food ready for instant use; that may be so as regards water, but for other substances the digestive action of the roots is necessary." As he, in common with all other modern authors to which I have access, maintains that plants having root hairs feed only by those hairs, and as I take it for granted that most people will agree that root hairs are only of annual duration, and produced only on young growths, it seems clear to me that no root-action (by which I mean feeding by means of the root) can take place before these root hairs are formed.—WILLIAM TAYLOR.

PERMIT me to inform "Credo" that when I spoke of there being no such thing as stored-up sap "in the sense Mr. Taylor states," I meant Vines did not store it "like an Onion," as explained at page 528; or to be plainer, I meant that Vines did not lay up a store of food "the previous autumn" or live upon that without any assistance from the roots, as I took Mr. Taylor up to mean at the beginning, and which declaration he has not withdrawn. If "Credo" understood me in any other sense I am sorry, but I thought that the whole discussion showed what I meant. That being so I have nothing to "withdraw." "Credo" will see that at the same page from which he quotes me I acknowledge Lindley's theory of storing up sap against the spring to be "the right one."

I notice "Credo" approaches the subject of the "elaborated sap" stores in a rather doubting manner this week. May I solicit a more precise and explicit reply to the last paragraph of my letter at page 528 in regard to the return of the elaborated sap to the leaves? Does the elaborated sap of 1883 return to the leaves in 1884 in any degree, and where is the proof of it? By elaborated sap I don't mean starch alone.—NON-BELIEVER.

FEELING somewhat indebted to Mr. Taylor for his teaching relative to Vines storing up sap and making considerable growth the following spring before root-growth commences, I take the present opportunity of thanking him. The readers of this Journal will no doubt remember the many able articles which have appeared in its columns on Vine-lifting, advising deferring the operation until growth had started. Well, as I wished to lift a whole house of Vines, sixty in number, all planted inside, I was led to consider very seriously what Mr. Taylor had advanced on the stored-up sap question. Lifting sixty Vines after pushing into growth seemed to me to be a very dangerous affair, as I wanted to pave the bottom of the border with tiles and Portland cement to prevent the Vine roots passing into the clay, as they had done, making it difficult to thoroughly ripen the fruit. All this work would occupy much time, and in the month of March, when we hope to have bright sun and a dry atmosphere, it would not be an easy matter to keep the roots moist during the operation, and there would be the danger of knocking off small shoots; but if, as Mr. Taylor says, Vines burst into top growth a considerable time before the roots start, why not lift the Vines soon after the foliage falls? Having confidence in Mr. Taylor's statements, I set to work soon after New Year's day, taking plenty of care and time, and secured splendid roots. The result was quite as I expected, for in March every one started growing as if they had not been moved until the shoots reached about 6 inches in length, when they suddenly stopped top growth for nearly a fortnight; but as soon as the roots took hold of the border they went ahead to my entire satisfaction, ripening about half a crop of good Grapes, proving to me at least that Mr. Taylor is in the main right. Having turned his advice to practical account I will again beg him to accept my thanks, and subscribe myself—A BELIEVER.

LIKE many more I have read with considerable interest the writings on this subject, and would gladly have continued to read them could those able contributors have seen their way to go further, or equally glad

to have seen it concluded in a satisfactory manner. It is to be hoped that it was nothing but a desire to benefit lookers-on practically which prompted "Non-Believer" to lodge his objection, for I fail to see what benefit can be derived by trying to expose the failings of any writer unless abundant proofs are brought forward.

I write to say only a few words on the subject, for speaking generally I am of opinion that although most gardeners who attain to positions of importance are very practical, yet we are not able to go far scientifically, and in that respect may expose ourselves to many lookers-on, who, though they could not pot, plant, or prune a Vine, could give us much information on other plants. It has often been my lot to practise where Vines have been very successfully treated, and have always been a close observer of their habits, and venture to think with our practical friend, Mr. Taylor, that the first growth produced on Vines, which of course varies considerably, is from stored-up sap, and to this I mainly attribute the weakening effects produced on some Vines which are forced compared with those which have been well ripened and prepared, and those allowed to start themselves. The latter in many cases have numbers of fibrous roots by the time growth commences, and sooner assist in developing the foliage, whereas those forced early drain the supply in store before root-growth begins; yet to suppose that the numerous fibrous roots which Vines in good condition have are doing nothing seems absurd. It has always been my impression that as the foliage matured and ripened for the fall of the leaf, so in proportion did the white or hair roots disappear and the hosts of fibres left naturally sufficient to keep up the supply already stored, or in other words to prevent it diminishing.

As some little confirmation of this view I will endeavour to relate a few instances which it was my not-very-pleasant lot to witness some years ago in the month of March, I having taken charge in the previous July. "Ah!" some may say, "all wrong the first year; always so with a new gardener." These Vines had been neglected for some years, and at certain times, perhaps, treated too liberally, been started at 75° to 80°, and expected to bloom at 55°, with roots inside and out, and were then about ten years old. Soon after taking charge the remainder of the crop was cut. The leaves were quite ripe and fast falling. The Vines were in due time pruned, and started about the middle of January, and owing to their extreme weakness at the top were tied straight up in their places. The buds began to move in about a fortnight, strongest at the bottom, and eventually the foliage expanded, but before it reached the measurement Mr. Taylor speaks of, one fine Sunday morning I was almost paralysed to notice several shoots on every Vine suspending from the spurs, for not many had grown enough to tie to the wires. As the next few days were dull they appeared to recover, but only to succumb again on the return of bright days. The only plan suggested was to cut the Vines down to within a couple of feet from the ground, in the hope that they might break and produce young canes. They did not bleed after amputation because the leaf-growth had used all the stored-up sap, and a close examination at the roots showed there were few or no fibres to supply more.

By the middle of May it was evident that no strong shoots were coming from these often-viewed remains, and the Vines were removed, when not a fibre could be found. Now I would ask anyone who disbelieves in stored-up sap, What did these Vines exist on even so far? I maintain they existed on the sap of the previous year, and when that was exhausted, and no fibrous roots to produce the necessary supply, the Vines died.—E. B.

ALTHOUGH Mr. Taylor may not be strictly accurate in the terms he has employed in the discussion on this interesting and important subject, there are probably not many readers who do not feel that he is substantially correct in the views he has enunciated. His statement that the laterals of Vines are dependent on the stored-up sap in the rods for support until the growths are 7 inches long and the leaves 4 or 5 inches in diameter cannot be maintained if applied to Vines generally, though his vigorous and well-matured canes may possess sufficient stored-up nutriment to enable them to do what he has stated, but not without a supply of moisture which the roots absorb from the soil, whether the cellular hairs are formed on them or not. In all probability he is right that these root hairs are not produced before the expansion of foliage, and that they wither with the fall of the leaves; and if that be so we have conclusive proof that the roots imbibe moisture independently of those annual appendages, in the excessive bleeding of many Vines before the unfolding of the smallest leaf. Whence comes this fluid if not from the soil? and yet the root-hairs then are "non-existent."

The truth about the matter appears to be this. Sap or watery fluid is not stored in Vines to any appreciable extent in winter, but is essentially the vehicle by which food is conveyed; the water, which composes at the least 90 per cent. of the volume of what is termed sap, being dispersed by transpiration, the nutritive matter being deposited in the stems as a food store for incipient growths. Vines, therefore, do not store up sap in winter of the nature of that which escapes from bleeding canes in the spring; but they store the food that the sap has conveyed and the foliage prepared, and this is diluted and rendered actively nutritious by further imbibition of water by the roots long before any leaves, and consequently, according to Mr. Taylor, long before any root hairs are formed. I shall be a little surprised if, on reflection, your correspondent seriously quarrels with this view of the case; and may almost venture to assume that if it had been so stated at the first "Non-Believer" would not have felt constrained to have seriously combated the statement.

As to the amount of matter stored, and to what length it will support growth, depends entirely on the strength of the Vines, the development

and activity of the foliage, and the absorption of food by the roots during the previous summer. In the case of hundreds of Vines the food store is not more than sufficient to support an inch of growth, while in hundreds of others there is sufficient to support growths of five times that length, for the simple reason that there is five times more nutritive matter deposited in strong matured Vines than in weak, ill-fed, and immature canes. This can, no doubt, be demonstrated any day by a competent microscopist. Thus both your correspondents may be wrong and both right on this point—one in saying the stored-up sap is only sufficient for fairly starting the growth of Vines, the other in asserting it will support the growths until they are several inches long.

The discussion, so far as it has gone, and perhaps it is not finished yet, has been without doubt instructive to many, and possibly even to the two able leaders in the controversy. It is true a little "feeling" has been exhibited in the matter, but not to an extent harmful to either; and in this matter it will be conceded by impartial observers that it is not easy to determine on which side the virtue of restraint has been the most prominently exhibited; but most experienced readers will agree that those who cultivate that virtue the most usually strengthen their position in any controversy.

If, perchance, any should fail to perceive the benefit of a discussion on the subject under notice, their obtuseness cannot but be regretted, as the question of storing-up nutriment by Vines has a direct, important, and practical bearing on the routine of successful Grape-production, as perhaps some competent "modern scribe"—if there be one left—will show on some future occasion.—*Not H., Notts.*

TREE CARNATIONS.

TREE Carnations are amongst the most useful plants we have for supplying cut blooms during the winter and spring months. They can also be had to bloom during the summer if required. But it is in the winter and spring that tree Carnations are the most useful, as during the months of July, August, and part of September the beautiful show varieties are in full beauty, and none need be short of choice cut blooms during those months if they have a stock of Carnations, Picotees, and Roses. Tree Carnation blooms are much appreciated for buttonholes and bouquets, as they last a long time when cut. They are also well adapted for the embellishment of the conservatory or dwelling house, as they continue unfolding for months.

If anyone wishes to raise a good stock, and has no plants to produce cuttings when the time for propagating arrives, he should procure a plant of each of the best varieties from a nurseryman who makes a speciality of them. If the plants are required for blooming during the winter the cuttings should be taken about the end of February or early in March and inserted in sandy soil, using well-drained pots. Place them in slight bottom heat, and top heat about 55°, and if kept moist they will soon form roots. Insert them singly in small 60-size pots in the same temperature until April, when they should be transferred into 48-size pots. The soil at this potting should consist of four parts loam, one part well-decayed manure, and one of sand, with a little charcoal broken up fine. Arrange them in a cold frame kept rather close until they are established and growing freely, when it should be well ventilated. In May place them in the open air, but not until the May frosts are over, so that the end of the month would be preferable. If large plants are required transfer the most forward into 7-inch pots, but keep them under cover until established.

Carnations require careful watering during growth; in fact, at all times. The following are a few good varieties:—*A. Alegatière* (red), *Miss Jolliffe* (pale pink), *The Queen* (white), *Proserpine* (scarlet), *Firefly* (scarlet), *Mrs. George Hawtry* (yellow), *La Belle* (white), and *Warrior* (scarlet).—*A. YOUNG.*

DEATH OF MR. THOMAS SPEED.

It is our painful duty to record the death of the above excellent gardener, whose name has long been familiar to most, if not all, of our readers, by the high position he occupied in the ducal establishment of Chatsworth. So painful has been his life of late years, and so melancholy its termination, that we are reluctant to dwell on one of the saddest events in the modern history of gardening. Left a widower with a large family, and an almost constant sufferer by an excruciating affliction, gout, he in a moment of temporary insanity shot himself on the 26th ult. At the inquest at which the above verdict was recorded medical evidence was adduced showing that the remedies that he had been employing for the alleviation of pain had a tendency to produce mental depression; and this appears to have been the fact, as was evident by his changed demeanour in transacting business with the steward, and by his conduct at home, as observed by his sister shortly before the occurrence of the dire event. Still there was no cause for alarm, nor any apprehensions that anything serious was about to happen. He retired after dinner as usual, a noise was heard, and an alarm raised, but he expired before the room was entered.

Previous to taking charge of the gardens at Chatsworth (in 1868) Mr. Speed was gardener to Sir Edward Walker, Berry Hill, Mansfield, Nottinghamshire, where he gained considerable fame as a Grape-grower during the years 1859 to 1868. He had also served some time at Belvoir Castle and Wrotham Park, where he laid the foundation of the practical knowledge he subsequently displayed. His earliest experience

of specimen-plant-growing was gained at The Pymmes, Edmonton, which about the years 1850 and 1851 was one of the most noted establishments in the neighbourhood of London.

Mr. Speed was born on December 19th, 1832, and he was therefore fifty-one years of age at the time of his death.

VEITCH'S IN 1853 AND 1883.

THIRTY years ago on a certain day in December I visited the Royal Exotic Nursery at Chelsea for the first time. I was then a mere youth, but certainly not less earnest in my search for excellence in the culture of plants than I am now, and was possibly more observant. The astonishment felt at the number of houses and great variety of plants made a deep and lasting impression. I was bewildered and perplexed, even almost daunted, as a sense of fear overcame me that I should never attain the knowledge that I felt requisite for a gardener—namely, that he should not only know the names of all the plants in that great collection, but be able to grow every plant satisfactorily. As time passed the majority of the plants and their culture became familiar to me, and some others that were not seen then but which are indispensable now. Hardwooded plants were then predominant, and the flowers of the period consisted mainly of Heaths, Epacris, Camellias, a few Acacias, with early Rhododendrons and Azaleas. There were also tall Poinsettias with gorgeous heads, not dwarf plants as now; Epiphyllums, very beautiful; Primulas in quantity of the old "mill sail" type, not the massive richly coloured forms of the present day; with some tall Cinerarias, made taller by forcing, and a remnant of Chrysanthemums, also a few of those rare and wonderful plants Orchids. The display was for the time considered imposing, and the astonishment of visitors was great to find so many "flowers in winter."

Last week I had the pleasure of inspecting the same nursery. As it was considered a "great place" in 1853, what can be said about it after its generation of steady growth? It is wonderful by its hundred houses and their intricate arrangement; threading our way amongst them is like traversing a maze. Numbers of these structures visitors never see, and certainly they could not be found without a guide. Yet even now the establishment is growing, and new erections are constantly in progress. Apart, then, from other nurseries, the increase of this one demonstrates in a striking manner the extraordinary expansion of public taste in the direction indicated. Plants and flowers by nearly all who can afford to have them would appear to be regarded as necessities of life, and those that are attractive during the winter season being particularly esteemed. Of these a feast is now to be seen at Chelsea.

In 1853 there were no Cyclamens, but these are splendid now—wonderful in vigour and variety. There were no winter Carnations then, but now a large structure is wholly occupied with thousands of flowering plants; and what were then little more than curiosities—Orchids, now constitute the most splendid feature of the establishment. The Odontoglossums are a sight, a great and beautiful sight, in themselves—a forest of arching spikes and richly spotted flowers, relieved by rich glossy foliage that the most advanced enthusiast of thirty years ago never dreamt of seeing in "dreary December." Then the *Cypripedium* arrest attention, as well they may, by their striking forms and remarkable combinations of colour. A mass of sixty flowers alone of the peerless *Spicerianum* on a batch of plants was something to see and remember, to say nothing of the many charming and interesting varieties that were born on the premises. Of *Cattleyas* there are but few flowering, yet these are gorgeous; but 400 uprising sheaths are premonitory of future magnificence, and there is a similar bright prospect of *Vandas*, *Aerides*, and *Saccolabiums*, which are bristling with spikes. Great white flowers of *Angraecum sesquipedale* are expanding, and very lovely is *Lælia albida*, with scores of other charming companions constitute a display of no little beauty even in dull December and January. Of special interest, however, amongst the Orchids, though now past its best, is the handsome hybrid *Cypripedium calurum*, which was honoured with a first-class certificate at the last meeting at Kensington. It is one of the popular *Sedeni* group, and possesses the valuable characters of vigorous growth and a floriferous habit, the neatly formed flowers with full rounded deep rose lip and pure white petals and sepals having a unique appearance. Much good service has been done in this section of *Cypripediums*, which are becoming great favourites with Orchid growers generally. Large numbers of seedling Orchids are constantly being raised in these nurseries; and though much patient waiting is required before the results can be seen, the long-continued efforts now bring annual additions to the already long list of beautiful hybrids that have been originated by the firm.

Nepenthes both in numbers and variety produce a spectacle altogether unique, thousands of pitchers hanging from the plants and rustling against each other by the slightest movement. The famed *N. Northiana* is developing, but nothing in the houses is more striking than the free and rich *N. Mastersiana*. This is indeed a grand acquisition, and not many plants more remarkable, distinct, and meritorious have emanated from this great plant emporium. Then there is the wonderful *N. bicalcarata* with its two strong and peculiar spurs at the mouth of the pitcher. *N. madagascariensis* is an exceedingly brightly coloured form of the *N. sanguinea* type, the pitchers about 7 inches long and very numerous, even on small plants, which, by the way, are dwarf and sturdy in habit as compared with many others of this family. *N. Morganii* is a very attractive hybrid, with green and red mottled pitchers gracefully formed and abundant. But the most extraordinary of all is the giant *N. Rajah*, which, though not yet represented by pitchers in their full proportions,

gives hopes by its rapid advancement of soon reaching gigantic dimensions. When fully developed these are 12 inches long and 6 inches in diameter, very hard and full. Many others could be enumerated, and the distinct *N. Veitchi* must by no means be omitted, as it takes the attention at once by its beautifully formed pale green pitchers. *N. sanguinea* is also one of the thoroughly useful sorts, bright in colour and very free.

Stove plants, including a wonderful collection of handsome *Crotons*, *Anthuriums*, *Alocasias*, and multitudes of other choice flowering and fine-leafed plants occupy dozens of houses, and would require a volume to enumerate all their attractions. The same might be said of the soft-wooded and greenhouse department, in which all the more popular and useful plants are grown by thousands.

A grand house of tree Carnations has been for some time a great feature amongst these, and proves how valuable such plants are at this time of the year. A perfect forest of flowers is borne on strong but compact plants, which continue for a long period in good condition, and yield a constant supply of fragrant and useful flowers during several of the dullest months of the year. The most notable of the varieties are *A. Alegatière*, dark scarlet; *Irma*, bright clear rose, very pretty; *La Favori*, rosy scarlet; *Falstaff*, a bright purple flake; *Laura*, salmon-pink; *The Bride*, pure white; *L'Hermine*, white; *Miss Joliffe*, pale pink; *Lucifer*, deep rich scarlet; and *Andalusia*, yellow. Conspicuous above all is, however, the superb new variety *Mrs. Keen*, which was recently shown at Kensington and honoured with a first-class certificate. This is an extremely handsome form, with massive flowers of an intensely deep rich velvety maroon colour, which in some lights appears almost black. It is of strong habit, very free, and is certainly one of the grandest of the type.

The plants mentioned are only a few of the many flowering in the nursery during the last week of 1883. How different from the appearance of the house during the corresponding week thirty years ago! The progress is astonishing, and progressive still.—A COUNTRYMAN.

WILTON HOUSE.

WHEN in Wiltshire last September I was urged by every gardener I met not to miss an opportunity of visiting Wilton; and one friend, who had evidently taken the measure of my capacity, had the honesty to remark, "You will learn something there." It is true he did not appear to fully comprehend the significance of his observation until a few minutes after its utterance, and would evidently have withdrawn it if he could. Yet it was true. There is scarcely a well-managed garden to be found where there is not something to be learned, and there are, I may venture to say, few men who could spend an evening in the well-appointed gardener's residence at Wilton without adding something to his store of knowledge. An outline sketch, therefore, of Wilton, its grounds and gardens, may not be unacceptable; and if the details be necessarily scant, this will afford an excuse for those who are able to do so to go and see for themselves—this fine old English home of an old and noble family being well worth a visit by archaeologists and gardeners.

Wilton, then, the ancestral seat of the Earl of Pembroke and Montgomery, is about three miles from Salisbury; but there is a railway station within a mile from the gardens, the route in summer being almost under a canopy of foliage, all the roads that intersect the demesne apparently being lined with grand timber, which, more than anything else, imparts dignity to the surroundings of the homes of the affluent. Wilton is one of the most ancient, as it is now undoubtedly one of the smallest of parliamentary boroughs, famed for its carpet manufacture, and perhaps largest annual sheep fairs in England. The *Wylie*, which runs through the grounds, is supposed to be the first river in which trout and grayling were established in England by the monks of old. Established they certainly are, and it is a pretty sight to see them in shoals gracefully gliding through its pellucid waters.

Another river, the *Nadder*, a more imposing stream, also intersects the pleasure grounds, and is spanned by an elegant bridge with an open Ionic colonnade, which forms a striking feature from the mansion as viewed through the branches of magnificent Cedars of Lebanon. These trees are the pride and glory of Wilton. There is quite a forest of them on the great lawn, four of them being regarded as among the oldest trees in the country, having been established 200 years. How majestic such specimens are with their firm trunks and rich deep solid green branches! Perhaps the oldest description of this tree is the best, that by the prophet Ezekiel:—"Behold . . . a Cedar in Lebanon, with fair branches, and of an high stature; and his top was among the thick boughs. His boughs were multiplied and his branches became long. The Fir trees were not like his boughs, nor the Chestnut trees like his branches; nor any tree in the Garden of God like unto Him in beauty." Such, then, are the Cedars at Wilton—none equals them in beauty.

The two rivers running through the grounds indicate that the position is not elevated, also that the land is fertile—natural advantages that never appear to have been overlooked by the shrewd old monks in the selection of sites for abbeys and monasteries. Wilton at a very remote period was the seat of a monastery, an oratory being first erected by *Wulstan*, Earl of Wiltshire, whose widow succeeded in raising it into a priory; and King Alfred, after his defeat of the Danes, is said to have erected a nunnery and transferred it to the sisters of the priory. Here the Queen of Edward the Confessor was educated, and *Maud*, Queen of Henry I., passed many of her early days. It was taken possession of by King Stephen 740 years ago, but he was driven out by the army of the Empress *Matilda*, by whom it was destroyed by fire; it was eventually

rebuilt. In 1579 it was visited by Queen Elizabeth, and a quarter of a century afterwards was for some time the residence of the Court. That is, in brief, what history records about the ancient manor of Wilton. At the dissolution Wilton Abbey was granted to Sir William Herbert, afterwards Earl of Pembroke, who on its site commenced the erection of the present edifice from designs by *Holbien* and *Inigo Jones*.

It is a massive pile of great magnitude. The exterior is not remarkable for architectural embellishment, but the interior is exceedingly rich in ancient and modern statuary and rare old paintings—notably the *Vandyke room*—and with plants and flowers, of which Lady Pembroke is an ardent admirer, tastefully disposed in every available position, an effect is produced such as is rarely seen. The plant-furnishing is a work of magnitude at Wilton, and right well it is done. The views from the windows over 65 acres of lawn well furnished but not crowded with grand deciduous trees and evergreens, with the river glistening down the valley, leading the eye to the distant and lofty spire of Salisbury Cathedral on the one hand, and the flower garden and isolated temples beyond on the other, are of no ordinary character. The flower garden is what may be termed a small corner masked on all sides by evergreens.—a bright spot in a great framework of green. It is pleasingly diversified with shrubs and vases, and is gay without being severely formal by the disposition of the plants in spring and summer, spring gardening being carried out on an extensive scale.

To attempt an enumeration of the trees and shrubs in these extensive pleasure grounds would simply result in an imperfect catalogue; therefore only just one tree will be noticed—an old and lofty Horse Chestnut that made a mistake a number of years ago and has never been able to rectify it—namely, it partially casts its leaves in summer instead of in autumn, makes fresh growth, and flowers in October instead of in spring! This is its invariable habit, its neighbours around it being content to progress in the orthodox way. Between the mansion and kitchen garden an antique building half hidden among the trees arrests attention. Ancient it undoubtedly is, and picturesque, yet useful, for there the children of workmen on the estate are clothed and educated by Lady Pembroke, who further seeks to obtain for them good appointments in life. It is truly "noble to be good."

The kitchen garden is about a quarter of a mile north of the mansion, the *Wylie* forming the southern boundary of the department under notice. The stream is crossed by bridges, and in one part by large stepping stones which rise a few inches above the water. These stones have been used from time immemorial, presumably from the "days of the Romans," and on that account are not likely to be supplanted by a modern bridge. The stream, which is somewhat rapid, has been turned to excellent account by Mr. Challis, as by holding up the water at a convenient point, making a water wheel and fixing pumps, water is forced all over the garden and houses at the least possible outlay, and can be brought to bear in washing wall trees and watering crops through moveable tubing. This is a very complete arrangement, and an ever-present supply of water is insured at a trifling cost considering the extent of ground through which the pipes are conducted.

The most commanding feature of this garden is the great collection of fruit trees, which, however, do not impress so much by their numbers as their splendid condition. Pyramid Pears especially are magnificent, the main avenue being highly imposing. They are not pigmy trees, not a few of them being capable of bearing fruit by the bushel. They range from 15 to 20 feet high, are perfectly furnished to the ground, and as symmetrical as the most ideal Conifer that can be imagined. They are systematically and skilfully pruned, and periodically lifted, or they could not be maintained in their present condition. In some soil fruit trees may be planted and afterwards almost let alone, with the assurance that they will make handsome specimens and in favourable seasons afford bountiful crops; but this natural system would fail utterly at Wilton, where the soil is only slightly above the water, as indicated by the streams. In such positions it is imperative that the roots of the trees be kept near the surface, and although summer mulching be practised, occasional lifting also becomes a necessity. This was demonstrated by several trees that were "waiting their turn" to be taken up and replanted. Immediately roots find their way into the wet subsoil the growths assume a totally different character. The leaves have a yellowish green hue and are thin in texture, while the growth is also thin, long-jointed, destitute of tissue, and essentially unfruitful. It is a great work keeping such a number of trees in order under these circumstances, and it is not always possible to attend to each specimen with the promptitude that is desirable; yet it is evident that none of them have to wait long for the attention that they need, and the result is as grand a lot of fruit trees as a gardener could reasonably expect to see under the most favourable conditions of site and soil.

Wall trees need similar care or they would not long remain in a satisfactory state. All the borders are aerated by a series of drains and vertical pipes protruding through the soil. Mr. Taylor, in his excellent work "*Vines at Longleat*," expresses a doubt that an arrangement of this kind conduces to the aëration of the soil, and rather suggests that it tends to the circulation of air in large streams through the pipes and from the soil. In a well-constructed, drained, and sufficiently porous Vine border air will always follow the water that is given, and the borders well managed remain sweet; but it is not so when, as at Wilton, the soil may be said to rest on the water. Artificial aid is then necessary, and that it works beneficially is evident by the improvement of those trees to which the system has been applied, and hence it is being extended as the replanting is proceeded with. Thus hardy fruit culture at Wilton is work requiring the exercise of much thought, sound judgment, and

judicious action; the trees indeed have to be regarded as so many specimen plants, and watched and treated accordingly. That they receive this care their condition testifies, and the success achieved becomes the greater since it is attained under the obstacles alluded to. Difficulties are opportunities that the man of skill and mettle covets, and to surmount or remove them is his greatest reward.

But there is a bird difficulty at Wilton as in other places, and if the spring frosts, which are very destructive in the damp valley, did not destroy the blossoms of Cherry trees there was yet no fruit for the noble owner. Both frost and birds have been successfully combated by one simple operation and inexpensive contrivance. Over a long row of pyramid Cherries a light framework of 2-inch deal battens has been erected. Posts are fixed at intervals above each side of the row and well beyond the branches of the trees. These uprights are 8 or 9 feet apart and slant inwards, meeting at the top within about 3 feet. This space is bridged with glass—just a double glass coping, formed by one row of large panes along each side fixed on the safe, simple, and excellent plan devised by Mr. Challis for glazing Peach houses and vineries. The upright posts are stayed by two rows of cross-bars, and the whole made rigid. The framework is then covered with small-meshed woollen netting. The result is the glass coping throws

shovelful or two of fresh soil, and thus the supply is maintained without much more trouble than is involved in growing Cauliflowers, while a fruit is usually ready when it is wanted. This may be termed Pine-growing-made-easy, and healthy plants and excellent fruit are produced. The next range is a three-quarter span about 10 feet wide, the path being under the ridge, a bed on one side for Melons, with hot-water pipes running round the top of it, and shelves on the other side for plants, such as Strawberries and Kidney Beans—one of the most useful and handy of structures for various purposes. In the other divisions are Vines grown on the extension system, yet the roots are confined to a border 3 feet wide and less in depth. Nothing could be more satisfactory, good crops of excellent Grapes being unfailingly produced, a variety known as Keynes' Muscat being highly prized. Particulars of the grand Peach range and a striking example of "growing Vines without soil" must be deferred till a future issue.—J. WRIGHT.

KEW GARDENS—YOUNG MEN'S ROOMS.

I WAS much pleased with the suggestions by "Veritas" in his "Notes at Kew," regarding the desirability of a suitable structure wherewith to display the beauties of the large number of half-hardy plants that are

FIG. 2.—WILTON HOUSE.

off heavy autumn rains, and the wood made is sturdy, matures, and is fruitful; shelter is also afforded from spring frosts, and the blossom sets, while the netted sides exclude the voracious birds. The value of the first crop of fruit exceeded the entire cost of this efficient protector, and it will answer its useful purpose for years. As a rule pyramid Cherry trees are comparatively valueless as dotted about in gardens, as the birds gather the fruit; but planted in a row and protected as at Wilton, disappointment ends, and the pleasure of gathering this much-esteemed fruit in abundance is enjoyed by the cultivator.

The "glass department" is extensive, the houses being admirably adapted for their purpose, and well arranged. They were designed by and erected under Mr. Challis's supervision, and although the system is not so complete as was originally intended, in consequence of the death of Lord Herbert, who was a great improver, the large portion completed has been done well. There is one relic of the past—a quaint old Peach house, with grand old octogenarian, perhaps centenarian, trees, but with this exception the structures are modern. Five ranges of pits and houses, most of them in three divisions, each 100 feet long, are most useful. The front range is a low narrow span-roofed pit with moveable lights, in which Pines are planted. When a fruit is cut a sucker is inserted in a

cultivated in pots and stowed away in pits and frames in the private departments. The hundreds of floral gems of a tender character that unfold their flowers in obscurity is, to my mind, lamentable, as 99 per cent. of ordinary visitors never see them. That a visitor has only to ask where particular plants are and he will be directed to them I grant, but thousands do not know for what to inquire, and these it is desirable to educate horticulturally. What better way is there of doing such a good work than by bringing together and displaying to advantage some of the neglected, and many of the comparatively unknown members of this class for plants?

In regard to the proposed accommodation for the young gardeners I think the authorities gave a similar suggestion consideration some years ago, and concluded that it was impracticable or undesirable, or both, from their point of view. I am cognisant of some of the most serious objections used against the scheme, and I frankly admit their importance, but I consider they are not insurmountable, and if there were the same desire to promote the comfort of the young men employed in the gardens as to advance other alterations and improvements I feel sure all obstacles would have been overcome long ere this. It is not absolutely necessary that the bothy or bothies should be in the gardens, but of course the

erection of a suitable building outside and within reasonable distance of the workmen's entrance would involve a greater outlay. That it is desirable to provide better lodgings for the young men there can be no question, nor do I think there is any doubt that British taxpayers would be willing to provide the few hundreds of pounds that would be required to carry out the scheme if the facts of the case were laid before them.

The Journal is therefore doing a good work in ventilating the subject, and I trust its columns will be open to a free discussion thereon until either the authorities have shown the impracticability of the suggestion or it has been carried to a successful issue. I endorse all that is stated by "Veritas," "Ex-Kewite," and "Experience," and knowing how powerless the gardeners at Kew are to help themselves it is a great pleasure to see their interests are not unobserved or uncared for by the horticultural press.—J. U. S.

In discussing a question of so much importance as the suggestion that the young gardeners employed at Kew should be provided with residences situated on the establishment, and under the control of the responsible head of the gardens, it is necessary that whatever reasons are urged in favour of such a proposal should be deduced from a careful consideration of the facts of the case, and with a due regard to the nature and object of the establishment itself so far as the young employes are concerned. That the subject is worthy of notice no one who has read what has already been stated upon it will be willing to deny. My knowledge of the establishment at Kew is, however, sufficient to warrant the opinion that the practicability of the proposed residences for young men is open to serious doubt. Whether what is done in many private establishments may be reasonably made use of as an argument in favour of the adoption of similar provisions for the young men at Kew, or whether the whole subject should be discussed on its own merits, is perhaps an open question, though in my opinion the two cases are not exactly parallel. So far as I understand the arrangements made for the quartering of the young men employed in large private gardens, bothies are provided at least as much for the advantage of the employer as they are for the employes. Most of such gardens are situated generally in the country, often a long way from villages or any houses where suitable and convenient lodgings for the gardeners could be found, so that to provide residences is an absolute necessity if a number of men are employed. Suitable quarters are always one of the first considerations with men employed away in the country.

In such gardens the stoking has to be performed by the under gardeners, which necessitates their being near at hand until midnight for at least a portion of the year. Again, the number of resident young gardeners seldom exceeds half a dozen, of which number perhaps two are foremen, holding responsible and semi-permanent positions, and they are supposed to exercise a proper influence over their companions indoors. These are but a few of the advantages of the bothy system in large private establishments.

In large public gardens, however, the case is totally different, none of the above reasons holding good when applied to their consideration. There the stoking is performed by men employed specially for such work; suitable lodgings are always within easy reach of the place; and the foremen are generally married men, or at least in a position to live in better circumstances than bothy life usually admits of. There is another important consideration in connection with the bothy question as applied to large public establishments—it has a serious moral side. To anyone acquainted with what generally happens when a large number of young, often inexperienced, men are housed together, if the supervision of such is not strict, and a severe régime enforced, the serious aspect such a question wears from a moral standpoint will easily suggest itself in the case now under discussion.

A year or so ago I had a conversation with a leading London nurseryman on the subject of providing comfortable quarters for young gardeners, where they could be looked after, and studious habits encouraged; and I was then informed that it had already been tried and had failed completely. One of our most eminent London nurserymen did undertake such a beneficent work, but in spite of the greatest liberality and care on his part the abuses of the bothy system when applied to a large number of young men were so great as to compel its abandonment. I suggested stringent rules and proper supervision, but was reminded that even young English gardeners loved freedom, and such rules would either drive good workmen away or result in much unpleasantness. Certainly this evidence went against any plan such as that suggested; and although we are too often made acquainted with cases of young raw men coming to London with the best intentions and being led astray and ruined by the vices of their surroundings, the proposal to undertake the care and control of fifty young men, who are not willing to be slaves to a strict discipline if they can avoid it, is a heavier task and a greater responsibility than most men are willing to deal with. So much for the bothy system.

Turning to Kew and the rules that govern the employment of young men, and the provisions that are made for their instruction and comfort, it appears to me that as compared with similar men in other large establishments they have little to complain of. The young men at Kew are supposed to have passed through the elementary stages of their profession before coming there to obtain an insight into the more scientific branches of horticulture. They are moved from one department to another, which enables them to gain a wide knowledge of plants, lectures on botany and allied science are given, and a good library is provided for their use in the evenings. The time they are supposed to stay at Kew is not more than a year. From this it will be seen that at some

sacrifice to the establishment itself Kew is made available to the young gardeners of this country for purely educational purposes; for the frequent changing from one house to another is not considered advantageous to the plant collections.

Now, whether rooms could be provided, or whether they would be considered advantageous to young men, even by the men themselves, is a doubtful question. It would seem that, apart from cost, private lodgings are more conducive to studious habits in a place like Kew, with all the advantages of the establishment itself, than any bothy system could be. Even if bothies were decided upon, whether the authorities would be willing to undertake the serious responsibility attached to the bothy system on a large scale seems highly improbable. The question of wages is one that concerns labour, and when compared with other large establishments Kew stands favourably.

The statements that have been made with regard to meal times are hardly worthy of notice here. Three-quarters of an hour are allowed for breakfast, and an hour for dinner, which are quite sufficient time to enable the men to walk to their lodgings, if in Kew, and get their meals comfortably. If anyone ran twenty minutes each way he could not have lived in Kew, or must have run a long way "round."—LIBERTAS.

THE letters that have appeared in reference to this subject have so far been favourable to the scheme, with the exception of that from "A Boss" in the last issue of the Journal (page 547), who seems to regard the idea as undesirable. As, however, he is evidently unacquainted with the peculiar disadvantages attending the present system of lodging the young men at Kew, I will extend my previous remarks in explanation of the case, and leave your correspondent and others to judge whether there "is anything to complain about."

Without attempting to raise a sensational discussion, such as the "Bitter Cry of Ill-used Gardeners," or anything of the kind, the facts are briefly as follows. In the first place the lodgings are mostly too distant from the work, and from twenty minutes to half an hour or more of the time devoted to breakfast and dinner is occupied in "running" to and from the houses. This in itself is a great disadvantage, and one that can only perhaps be understood by those who have experienced the evils produced by it. Then as regards the lodgings themselves, if they were really "quiet and private," as "A Boss" supposes them to be, study could undoubtedly be more readily followed up than in "a noisy barrack room." Unfortunately, however, the peaceful quietude that would be so conducive to study exists only in the imagination. For example, one friend of mine had the misfortune to be located with a family including seven young children, who "breakfasted" and "dined" at the same time as himself, and during the evening and often until early morning some were usually in various stages of trouble, which they expressed in the customary harmonious infantile manner. The progress this young man made with his studies in his "quiet private lodging" was astonishing; happily, however, he secured a fresh location before he was past recovery.

Another instance. A young man of studious habits, one who had raised himself high in the estimation of his superiors, occupied a room in the upper portion of a house, and immediately below that was another lodger who was afflicted with a mania for concertina playing, but whose taste for music was undeveloped. The nightly agonies of the would-be student can probably be better imagined than described. A creaking mangle in frequent use in an adjoining room "A Boss" might also consider beneficial, but what would he say to the mental effects produced by a piano under the tender hands of a persevering young lady in her teens? An intimate friend who enjoyed a strong mind and a robust constitution endured this for several months, but he mentions the matter with a shudder. These are only a few instances which I could multiply by tens, for several of the houses where the young men lodge are the conventional Kew "Tea Houses," and throughout the summer months the visitors occupy so much of the proprietor's time that the "lodgers" have in a great measure to look out for themselves, and the noise and bustle continue until late in the evening.

But a more important matter in a sanitary point of view is the condition of the rooms, and it is only fair to say that generally they are clean. There are, however, serious exceptions, and one row of houses has long since gained a *sobriquet* indicative of the particular kind of insect life most abundant there. In another row the lower apartments of the houses are below the level of the river at flood tides, and in past years have been frequently swamped. Some of these are little better than cellars. In one, which was occupied by an excellent young man (now head gardener to an English nobleman), boots, boxes, and everything placed on the floor or in the cupboard became in a day or two covered with a thick mould. What visions of rheumatism and allied ills does this bring before us?

Then as to the expense, it would be quite within the mark to say that as a rule these lodgers have to pay 10 per cent. more than the average London prices for provisions, and this, be it remembered, out of 16s. per week. I should not like to make a general charge against the landladies, because a few are, I believe, conscientious, but the majority seem to regard the young gardeners who go to Kew as possessing an unlimited supply of money, which it is necessary they should assist in dispersing. Few leave Kew much better off pecuniarily than they entered it, and in my early days I have saved more in a bothy at 12s. a week in three months than I could do at Kew in eighteen months. It is true that most of those gardeners who enter Kew do so for the sake of the special knowledge to be gained there, but it is hardly in accordance with the traditions

of a great and wealthy empire that its noblest garden should be maintained in order at the expense of those employed to do it.

"A noisy barrack room" "A Boss" thinks would be unsuitable to study. Undoubtedly it would, but who has proposed a "barrack room?" The reading-room at present devoted to the purpose of study is amply sufficient, and the order which prevails there is the best example of how young gardeners can associate together with one object in view without indulging in horseplay and larking. At the room in question there is no one in authority to maintain order, though the young men take it in turn week about as clerk, whose duty consists in opening the room, admitting the men, and seeing that the books are all returned to their proper places each night. Yet with all this freedom the men show their good sense and appreciation of the privilege accorded them by preserving the most exemplary order. Should any employé break the rules in this respect he would be reported to the Curator, and if the offence were repeated he would be in danger of being discharged. This is all the check imposed, but it is amply sufficient.

The whole routine of duties and studies at Kew is an excellent training for any young man, and scores who now fill responsible positions look back with satisfaction on that part of their experience. Strict punctuality, civility, and attention to duties are enforced, and in addition all are expected to take advantage of the opportunities afforded of extending their knowledge of plants and plant life by attending the reading-room frequently and the numerous courses of lectures, the notes taken at the latter having to be written out and submitted to the lecturers for approval and comment. The authorities are thus enabled to see at once whether the young men comply with their requirements. If they do not they spend their time at Kew to little purpose, for their testimonials will bear the record that they "have not availed themselves of the opportunities afforded them."

Study is therefore in a measure compulsory, and it appears to me that the least which can be done is to assist in rendering it as little taxing to body and mind as possible. Convenient residence in the gardens near to their work, the lectures, and the reading-room, with better quality food, better cooked, and at a more moderate price, would be a most important assistance to the young men in every way. The primary cost would be small as a national work, and it could be subsequently made entirely self-supporting.

The whole question turns upon two points: First, is the accommodation advocated needed? and secondly, is the scheme practicable? The evidence already tendered has some bearing on the first, and if the men at present employed could proclaim their desires uninfluenced by the officials, nine-tenths, I am convinced, would be in favour of it. Those who would object to the few but beneficial restraints that would be necessarily imposed upon them are precisely those who would most need curbing. Presuming, therefore, that some improvement is requisite, the practicability of such a plan next demands consideration. What objection have the authorities at Kew or others to offer under this head? —VERITAS.

STEVIAS.

In these days of single Dahlias and glaring giant Sunflowers we are apt to lose sight of many old garden friends, and plants cultivated with pride previous to the mania are either left to themselves or are lost to cultivation altogether. That general cultivators soon lose an interest in plants that require a little extra attention is very obvious from their scarcity in gardens. Among the neglected plants no prettier genus exists than *Stevias*, a small genus of Mexican plants nearly related to *Eupatoriums*, although of very superior horticultural value. In point of beauty and compact habit they compare very favourably with many of the *Bouvardias*, and could be easily utilised for the same purpose—viz., greenhouse decoration at Christmas. It is true that they will not stand over a severe winter unless in a very dry and sheltered situation, but an ordinary winter does them no perceptible harm, even without covering.

The ordinary method of cultivation recommended is to grow them in large pots as specimen plants, plunge them out where desired in the spring, lifting them again in the autumn and wintering them in cool frames; and to most gardeners, whose time is a matter of consideration, the plan recommended above is no doubt in many ways very objectionable, and the result, to them, barely worth the trouble. A much easier and more satisfactory method is to treat them as ordinary annuals, simply sowing the seeds, which they bear profusely in spring, and when large enough for handling prick them into small thumb pots or pans, as recommended for tender annuals, and from thence to the beds or borders about the latter end of April.

Among the best for cultivating in this way are *Stevia amabilis* and *S. Plummeræ*, both rose-coloured; *S. ovata* and *S. eupatoria* both white. —D., *Stirling*.

PROPAGATION BY CUTTINGS.

In all private establishments a number of plants must of necessity be raised each year from cuttings, and this is undoubtedly one of the most important operations in gardening, yet it is very often carried out in a manner evidencing little knowledge of the work. So long as the cuttings strike it is considered satisfactory, no regard being had to the growth after striking, which in a great measure influences the plant, a healthy and vigorous plant rarely being the outcome of a weakly and indifferently rooted cutting.

Softwooded plants are usually those most operated with in gardens, and these are so readily increased by that means that little difficulty is experienced in keeping up the necessary stock for bedding-out or growing into specimens: yet it must have been proved to demonstration that a stout sturdy cutting taken off at the right time, neither too soft nor too hard, will be in a condition to emit roots freely and grow freely after it has become rooted, providing of course it receives ordinary care; whilst a weakly cutting, which from its hard growth has the wood much more solidified, and as a result roots tardily, is a long time starting into growth. It is extremely difficult, however, to convey an idea as to the exact solidity of the wood cuttings should have when detached. Many plants are exceptional as to the state the wood should be in when the cuttings are taken. As a rule the cuttings of most softwooded plants are in proper condition when the wood is fully a quarter and not more than half ripe; but much depends on the quickness the growths are made, as growths that are naturally made quickly will form roots from younger wood. For instance, cuttings of bedding *Pelargoniums*, *Verbenas*, *Lobelias*, *Salvias*, and *Ageratums*, which as stock plants are placed in heat in spring, will root more quickly than cuttings taken from outdoor plants in September, although the wood may then be apparently in the same condition as that of the cuttings from the heat-excited plants in spring, and the more succulent the cutting the less moisture it will need to insure its striking. It might be supposed that being softer it would need more moisture than a cutting with the wood in a much firmer condition. The contrary is, however, fact. The soft cutting is more capable of taking up moisture by the softer condition of the wood inserted, and that above has its pores more open, and takes in moisture more quickly, hence a moderate degree of moisture is only needed for such cuttings. A soft cutting will also need less shading than the firm, and as it will elaborate more quickly by its exposed surface an impetus will be given the descending current, and a callus with roots will be more quickly formed. The firm or hard cutting cannot withstand sun—it flags directly, and is soon beyond recovery. Its wood is hard, its pores are almost closed, and its channels narrow; it cannot take up moisture by the part inserted, and its leaves are so mature as not to be much refreshed by moisture, in consequence of which it needs more shade, more moisture, is slower in rooting, and seldom makes a good plant.

In propagating softwooded plants, which are by far the greatest number propagated in gardens, the cuttings are usually taken from plants in a growing state, and as a result a check of the severest kind is or would be given were they not placed under conditions best calculated to induce the formation of roots. This is most generally sought to be effected in the shortest time by placing the cuttings in bottom heat, and which of course must be suitable to the temperature the plant requires to grow in; and this ought not to be more excessive than that the plant needs as a maximum, whilst the top heat should be very little if any higher than that the plant is grown in from which the cuttings are taken. Anything much beyond the maximum of heat the plant needs to grow in as bottom heat is very injurious, especially if it be accompanied by corresponding top heat, which induces top growth, whereas every means should be taken to repress it, as growth in the cuttings without the formation of roots is most injurious. When roots are formed the cuttings will start into healthy growth, and need but a little hardening-off as compared with those struck in a much higher temperature, and as a consequence making much healthier and better-shaped specimens.

Then success in cutting-striking also depends on preventing evaporation from the leaves and stems, so as to prevent flagging and exhaustion. This is effected by means of a glass covering—bell-glass or handlight, frame, or propagating house, or a frame within that or some other house which prevents the moisture evaporating. Upon this moisture depends very much the success of the work. If the atmosphere be too moist the cuttings will in all probability damp, and if too dry they will flag. Without entering into the question of leaves absorbing moisture, it will suffice for all practical purposes to state that it is absolutely essential that the cuttings do not flag under any but very powerful sun, for if they flag on a dull day it is obvious the atmosphere about the cuttings is too dry, or the soil in which they are inserted lacks the needful moisture. In the case of very soft cuttings a slight flagging for a few hours when the sun is very bright will not do any harm, as it will check the tendency to leaf-growth before roots are formed, but it must not be allowed to be so excessive as to cause the foliage to dry. This condition of the cuttings we often see in the propagation of bedding *Pelargoniums* out of doors. The cuttings flag by day and recover at night, and everybody knows the result is more satisfactory than if the weather prove dull and wet. I am convinced that a certain amount of evaporation from the leaves or stems of the cuttings for a few hours each day is essential to a satisfactory result, and this, I think, takes place more or less under the influence of light, whether we admit air to accelerate evaporation or not, and there certainly is no harm in giving air providing it does

not lower the temperature beyond a safe degree, nor dry the atmosphere so as to cause the foliage to flag. It may cause the cuttings to be a little longer in producing top growth—an evident advantage, as this can be of no value until roots are present to support it. In fact, the rooting of cuttings depends on extremes in heat, moisture, and light being avoided.

There is great difference between making a cutting of a plant to root and growing a plant from a cutting into a specimen. If top growth takes place before the cutting has rooted it will never make a plant. Take, for instance, a Pelargonium, Fuchsia, or any other common plant; strike a batch warm, close, and dark. They will root most quickly no doubt, but they will be lank, tender, and need coddling to bring them round, during which they will have lost all that forms the nucleus of a well-formed healthy specimen. Strike another batch in the same condition as regards the cuttings, and give them no more top heat than is necessary to grow the plants, with a slight bottom heat to accelerate rooting, with moisture sufficient only to keep them fresh, and as much light as they will bear without flagging. They will remain stationary until roots are formed, and then grow quickly. Compare the results. Or take a more familiar example in the Chrysanthemum. Insert cuttings in December, place them in a position that top growth will not take place whilst roots are forming; and strike others in heat so that whilst roots are being made top growth has taken place to the extent of several inches. Take note of the results at blooming time, but there will be no need, as the difference will be marked all through growth. Plants that are to be grown into specimens should never be selected from those that have made considerable length of stem whilst roots are being formed, as it is a consequence of insufficient light, and growth made whilst this is excluded never after become sufficiently solidified to make good plants or flower satisfactorily. Much of the lank growth in cuttings would be obviated were the cuttings kept near to the glass. Light solidifies the growth. Shade is of course necessary with most plants whilst striking, but the less they have the sturdier will be the resulting plants.—G. ABBEY.

(To be continued.)

EUCCHARIS AMAZONICA.

NOT having for some days noticed your Stamford correspondent's request on page 508 respecting the above prevented me sending you an earlier reply. The compost we grow our Eucharis in is made up of about equal parts of peat and loam, with a small admixture of silver sand. The pots are well drained, as the plants in the growing season require water very frequently. We give them plenty of heat and abundant moisture over the foliage as well as at the roots. Before the plants can be induced to flower they must make a good and strong growth, after which there should be a gradual rest for a month or sometimes even more, when they should be kept dry and rather cool. I can scarcely state a hard-and-fast line. It is possible, and perhaps not an infrequent occurrence with persons who cultivate this, to have the plants in fine condition as regards health and vigour, but for want of duly resting or ripening the growth they do not flower freely.

About the month of May last I rested a large plant for about six weeks in a cold pit under glass. It was then put back into the plant stove, giving it plenty of tepid water at the roots as well as over the foliage. We wanted it for our local flower show about the middle of August, and it just came in in time. It was about a fortnight from the time that the flower spikes appeared until the plant was in full flower. There were thirty-five spikes upon it. After the plant was taken home it was placed in the conservatory till the flowers were gone. It remained in the conservatory longer than we thought it should have done before it was taken back to the stove again, as it lost a few of its leaves. But this second rest has caused other bulbs to flower, and just now there are twenty flower spikes again upon it. In a large pot of Eucharis there are always bulbs of various stages of development in it. The first and most important point is to get a good growth; then by forced rests they can be brought into flower at various times, though I have found that the tendency is for them to flower in autumn.—ROBERT MACKELLAR.

SPECIAL SOCIETIES.

REFERRING to the remarks of "X." at page 549 on the Pelargonium Society, it was first promoted and afterwards nurtured by the late Dr. Denny. Whether it was or was not really needed I will not stay to inquire, but there is no doubt that it has done a useful work and been the means of giving a great impetus to the culture of the Pelargonium. It was because of the good it was doing that I became a yearly subscriber to it, without any intention of becoming an exhibitor. The prizes were open to all the members under certain regulations, and but for the few, say three or four large exhibitors, the exhibitions as such would have been failures. The remark about prizetaking being almost a monopoly does not apply any more to the exhibitions of the Pelargonium Society than it does to those of the Royal Botanic, Royal Horticultural, or Crystal Palace Societies.

I am afraid it is "X." that would create a monopoly. It seems that

one or two leading growers sweep off all the leading prizes of the National Auricula, Carnation and Picotee Societies. "X." wants some regulation to prevent this. Pray what is that but creating a monopoly? Certain "daring spirits" have taken the highest prizes for a number of years. Say two or three individuals have done this. Of course it is very annoying to those who have only fourth, fifth, or sixth-rate plants. I mention these lowest scales, for the second and third-rate men make no complaint as a rule. How is it that all this complaint about the "big guns taking all the prizes" is only made about the special shows? Let us take the Royal Botanic Society for instance. I could point to classes in that Society's schedule where the same exhibitor has taken the first prizes in the same classes for at least a dozen years in succession. The only way to prevent such a glaring offence in future would be to say to such an exhibitor, "Friend, we have had enough of you and your exhibits; you had better keep them at home for the future." It would be a suicidal thing for any society to do this, nor did I ever hear of it being done; but it would let second-rate productions take a first prize if the judges thought them good enough.

Lest the remarks of "X." would lead some people to believe that the schedules of the National Auricula, Carnation, and Picotee Societies are arranged in the interests of one or two individuals, I enclose you schedules in order that you might see it is not so. The ordinary scale of prizes is first, second, and third, whereas the National Societies give six prizes in each class, and in that of the single specimens as many as eight prizes are given in one class. Further, in order to keep the great growers from competing against the smaller ones, exhibitors in classes A and B cannot compete in C and D. Perhaps you will hand the schedules to "X." to see if he can suggest any amendment. I do not know what else can be done, unless we tell the successful growers to keep their plants at home, and thus preserve a monopoly for inferior productions.—J. DOUGLAS, *Great Gearys, Ilford*.

[The schedules have been sent to our correspondent "X." as requested.]

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES.

THE following are the names of the Members of the Committees for 1884:—

SCIENTIFIC COMMITTEE.

CHAIRMAN.

Sir Joseph Dalton Hooker, K.C.S.I., M.D., C.B., F.R.S., V.P.L.S., Royal Gardens, Kew.

VICE-CHAIRMEN.

Col. R. Trevor Clarke, Welton Place, Daventry.
Rev. M. J. Berkeley, F.R.S., Sibbertoft, Market Harborough.
Dr. Michael Foster, F.R.S., Shelford, Cambridge.

SECRETARY.

Rev. G. Henslow, F.L.S., F.G.S., Drayton House, Ealing.

Balfour, Professor I. Bayley, Hillhead, Glasgow.	Lynch R., Irwin, A.L.S., Botanic Gardens, Cambridge.

TALL LOBELIAS.

By these I mean the varieties which have originated from *L. fulgens*, *L. splendens*, and perhaps *L. cardinalis*, and very frequently designated perennials, and indeed they may be, but that is a moot question. In certain soils and places they are scarcely biennial, while in others I have known stools to exist for several years. In the bog garden they are the longest lived, but under all conditions it is advisable to secure duplicate stocks, as they most capricious in their behaviour, and they are so distinct and showy that we cannot afford to lose them. To keep certain varieties true to name they are propagated by cuttings, the young shoots being taken off in spring and struck in gentle warmth, and they quickly form good plants. Of course such a method of propagation is indispensable where it is desirable to keep certain varieties separate, as in trade establishments. I have found them to very impatient of splitting up, having lost many plants after division, and they do not like to be kept without plenty of moisture. But where a particular variety is not so much a desideratum as a strong showy batch of plants the best way to increase the stock by seeds; and here let me say that if certain kinds are kept separate seeds collected from such will generally come true, but I think a slight variation in foliage and colour is very desirable in a bed of these plants, and to this end a packet of good mixture should be sown, usually under the name of *L. splendens hybrida*; from such seeds I have secured a fine display with many shades of colour, but all rich, and vigorous-growing.

To secure good flowering plants the same year the seed should be sown very early in the year, and the seedlings are very slow-growing until they reach a certain stage, when they make rapid growth. The end of January or early in February is not too early to sow; this should be done with care, as the seeds are exceedingly small, and by no means so free in germinating as the dwarf bedding Lobelias. Well drain the pots and fill with light sandy soil, water well before sowing, and sprinkle the seed thinly upon the surface, after which lightly cover with a little sand, and cover the pot with a piece of glass and place in a gentle warmth, either in the greenhouse or pit in a shady position. It may be necessary to give further waterings, which should be done with a fine rose or syringe, so as not to disturb the small seeds. When the seedlings show they may be subjected to more light, and when strong enough to handle pricked off in stoves, finally potting them singly, placing them in the cold frame, when they will grow quickly, and by May be quite ready to plant out whenever they are required.

As to the position they should occupy we must judge from circumstances, but they are decidedly much more effective *en masse* than as isolated specimens. I like to see them planted thickly together, and when a good bed is secured thick with the spikes of crimson flowers it is one of the most distinctive features possible to have in a garden, and it is in prime when many other plants are failing.—T.

LILY OF THE VALLEY.

THIS is one of the most valuable of all flowers in winter; but although it is sometimes had in bloom at Christmas I do not think it can be forced with profit or with the utmost satisfaction at that time. I have seen flowers in December with some good market growers, but they had special appliances for bringing them forward which few gardeners possess. It must be started very early to flower now, and only the very best roots and crowns will submit to this. Much heat, too, is required to develop it fully, and I would advise those who possess good roots to defer forcing until February or March, when they will have a much better return for their expenditure. Now the flower spikes would appear puny and be deficient of fragrance, with little or no foliage to garnish them, but

two months hence the pure white flowers will come with the most perfect fragrance and abundance of the most beautiful green leaves, for which we may look in vain at present. I have seen many fine pots of home-grown Lily of the Valley in bloom in March, and I have also seen imported roots in the same condition, so that both sorts are good, and lovers of this charming flower should try to improve the bought pieces by careful culture in summer. Roots required to flower two months hence should be in their pots by this time, and they may either be placed in a cold frame or under ashes like other bulbs for three or four weeks, and then plunged in a bottom heat of 80°, when they will quickly throw up their blooms and leaves in great profusion.—W. M.

CURL TAIL APPLE.

WE have already figured one of the curiosities that were exhibited at the National Apple Congress at Chiswick in the Scotch Apple, Stoup Leadington. We now introduce to our readers a Sussex Apple, which was exhibited in the collection of Messrs. Cheal & Son of Crawley. The form which is here represented is not accidental, for the specimens

Fig. 3.—Curl Tail Apple.

shown were possessed of this character. It is only fit for cooking, and the flesh resembles that of the Codlins.

CURL TAIL.—Fruit medium-sized, 3 inches wide and the same in height, inclusive of the prominent swelling at the stalk; round and flattened, somewhat obtusely angular, and with furrows at the crown. It has an extraordinary enlargement at the stalk, which curls round like a parrot's beak, which is russety. Skin straw-coloured, without any traces of red or russet. Eye closed, with convergent segments, set in a rather deep and furrowed basin. Stamens marginal or median; tube deep and wide, conical. Stalk nearly obsolete, being the point of the fleshy swelling. Flesh white, very tender, sweet, and agreeably flavoured. Cells obovate, abaxile.

An extraordinary-looking Apple, which possesses little merit, and is only fit for cooking. It is in use up till Christmas.

THE CONSERVATORY AT LONGFORD CASTLE.

At the present time the conservatory at this establishment presents an appearance which may very appropriately be described as interesting and beautiful. When it is mentioned that the inside measurement of this structure is 42 feet by 32 feet, with two large stages in the middle and one round the sides, it will at once be seen that to obviate the least semblance either to meagreness or overcrowding, an extensive collection of plants is required, which in health and appearance, together with their arrangement, reflect the highest credit on the gardener Mr. Ward. Its outward appearance is such as cannot fail to command a certain amount of attention from both builders and horticulturists. To the latter, however, it is that a brief notice in your columns of its occupants will be the most acceptable. Entering by the principal doorway the visitor's attention is at once attracted by the grand floral display of climbers. On the left we have *Lapageria rosea*, resplendent with its numerous and beautifully rose-coloured bell-shaped flowers, whilst on the right is its worthily congener, *L. alba*, flowering with more than its usual freedom. To give the reader

some idea of its floriferousness, we have only to mention the fact of having counted on the point of one shoot, and within a space of 15 inches, no less than twenty-three fully expanded blooms. Some people experience not a little difficulty in growing *Lapagerias* successfully; there, however, they appear to be quite at home. They are now throwing up strong and vigorous shoots, the tips of which remind one of young *Asparagus*. One shoot we measured was already upwards of 12 feet in length, and judging by present appearance, will doubtless exceed 30 feet. Like many other plants their culture is of the easiest when once understood. They are planted out in narrow well-drained borders, filled with a compost consisting of good peat and sandy loam in about equal parts. One point in connection with their treatment is, never allow them to become dry at the roots, otherwise disappointment will inevitably follow. When the border is well drained copious supplies of water should be given when they are making their growth. This passes through the soil quickly, without in any way rendering it stagnant or sour. The contrary is sure to be the case when the drainage is imperfect.

Of other climbers which adorn the roof, *Jasminum grandiflorum*, *Taesonias exoniensis*, and *T. Van Volxemi* are worthy of mention. The two latter are deserving of special mention, owing to the fact of their having been continuously in flower for a period of three years, a circumstance we should think unprecedented, unless it be in their native wilds. Such arboreal climbers are worthy of a place in any conservatory. Everything in the way of stiffness and formality in regard to training and tying is strictly avoided. The long streamers suspended in the air laden with their beautifully crimson-coloured flowers, each supported by its slender thread-like footstalk, are very pretty and have a decidedly picturesque appearance.

At the time of my visit *Chrysanthemums* formed the bulk of the pot plants in flower, the collections being well grown, and containing many of the best varieties, with every conceivable shade of colour from dark purple to pure white. Of scarlet-berried *Solanums*, *Eupatoriums*, *Primulas*, and other flowering plants there are quantities, as well as a host of miscellaneous fine-foliaged plants such as *Palms*, *Ferns*, &c., which need not be here mentioned. Under the stages, and raised somewhat slightly above the path level, are narrow borders planted with *Tradescantia zebrina* and other plants suitable to the purpose. Every available space seems to be utilised and made the most of to render the surroundings as agreeable and attractive as one could desire. It would seem superfluous to add that cleanliness and order prevail, and that the resources in the way of plant houses, pits, and frames, from which the supplies are drawn, are on a large scale.—ET-ÆTERA.

PEA CULTURE.

THE time is at hand when those who wish to get an early dish of Green Peas must in some way manage to start them. For a very early supply I have proved by experience that there is no better way than growing them in pots. The way I have done this, to the delight of my employer and the satisfaction of myself, is as follows:—In the first week of the new year I take 100 large 60-size pots and fill them with good soil, and place four or five seeds of American Wonder or Little Gem Peas in each pot, slightly cover and place them in a cold frame. They need to be looked to occasionally to make sure they are safe from mice. In other respects they do not need attention till they are fairly up, when they must be carefully watered. When about 3 inches high I pick out the most forward and transfer them to 16-size pots, using thoroughly good loam and a little decayed manure. After receiving a good watering they are placed on a shelf near the glass in a cool house, and need no special care to make them produce a good dish or two by Whitsuntide.

The remainder of this sowing are planted out in good soil in an ordinary cold pit, and simply grown by a judicious use of sun heat and an occasional supply of liquid manure from the farmyard, or a handful of Clay's fertiliser or some similar artificial manure as may be thought best at the time it is required. These make a capital succession to the pot plants, and are followed by others of the same sorts sown as early as convenient in February at the foot of walls with a south or south-east aspect.

For early supply in the open ground there is nothing that I know of to surpass William L., and for a second early I have found Hundred-fold a most servicable Pea. This has sometimes gone by the name of the Cook's Favourite and well does it keep up its reputation at this establishment. There are many other good and well-known sorts that could be mentioned, and which I have made a speciality of, but I will give my list with cultural remarks in another issue.—GEORGE MERRITT, *Gardener to Lord Daer*.

THE CEDARS, LEF.

THIS, formerly the residence of the late J. Penn, Esq., founder of the firm of J. Penn & Sons, Greenwich, who have gained a world-wide reputation in the construction of marine engines, now occupied by his widow, is one of those charming estates which in years gone by was famous for its Elm groves and very fine specimens of ancient Cedars of Lebanon, but now is gradually being encroached upon by relentless builders. It is also famous for its association with the poet Noble, who appears to have revelled in the then sylvan grandeur of its rural scenery. Here he was inspired to write "The Gipsies' Camp" and the "Cottage of Content." Could the poet survey the scene as it is to-day and compare it with that of the period when he wrote he would see a vast difference.

Villas have sprung up around, mushroom-like, and railways have intersected the estate since then. But although so much change has been wrought in its surroundings the gardens still retain their picturesqueness, and contain much that is worthy of note.

The pleasure grounds—there being no flower garden in the ordinary accepted sense of the term—comprising upwards of 20 acres, are charmingly situated on a gentle slope terminating in a valley, from which arises on the opposite side another slope equal in extent. The foregoing is laid out in the picturesque style with much boldness of design. Broad expanses of open and beautifully kept lawn and walks, with graceful flowing curves, avenues of noble Elms, with remarkably fine specimens of ancient Oaks, Cedars, &c., attract the eye as we stand on the terrace of the massively built mansion. The latter is clothed with climbing Roses, *Jasminum*, *Ampelopsis*, and Ivy. The last-named plant is a great favourite with Mrs. Penn. A large quantity is planted out in boxes on the balconies and porticoes, and allowed to trail gracefully down, thus having a most charming effect. At the south-eastern end of the mansion stands a neat little conservatory. This contains a fine specimen of Tree Fern, *Cyathea medullaris*, in the centre, surrounded by a choice collection of Palms and flowering plants in variety, all looking remarkably healthy and well grown. Near by are very fine examples of Cedars of Lebanon, said to have been planted during the early part of the last century. The branches of one, the largest of these trees, spread out to a circumference of nearly 200 feet. These seem to thrive remarkably well here, notwithstanding the injurious effects of London smoke, which of late years has swept down in such volumes as to almost entirely annihilate the whole of the Conifer family in this locality. Fine specimens of *Catalpa bignonioides*, *Picea Nordmanniana*, *Acer macrophyllum*; also Planes, Scarlet Oak, Chestnuts, and many others adorn the lawn. The shrubberies are well arranged and planted with a choice selection of shrubs. A great feature in these grounds is well worth noting: it is the employment of Ivy for covering around the bases of specimen trees. Many of us know how impossible is the task to maintain a green turf underneath large trees. Here this difficulty is solved by planting Ivy around the stems of the large trees, and pegging it down until it covers the bare space and forms a compact mass of dark-green foliage.

As I have previously mentioned, but little bedding-out is practised, and this some distance away from the mansion. What is done is simple and effective. An object worthy of special mention is the large and well-arranged Rose garden, which is situated to the right of the pleasure grounds. It is well sheltered from cold winds. Some thousand standard, half-standard, and dwarf Roses, embracing all the newest and finest varieties, are thriving in the best possible health and vigour. These were at the time of my visit (July) a glowing and varied mass of exceptionally fine blooms. It may be added that Mr. W. Penn takes a deep interest in the queen of flowers, and he is ably seconded in his efforts by the practical knowledge and assiduous attention of the gardener, Mr. Fox. Below this and hidden from the grounds is a large orchard of some few acres devoted to large standard Apples and Pears, both of which are carrying good crops of fruit. Stretching away to the left on the slope is a large and well-kept cricket ground. A large sweeping belt of shrubs is employed to keep the railway from view, which intersects one-half of the estate.

At each end of the grounds is a footbridge, over which we pass to the lake, a remarkably fine expanse of water, measuring about one-fourth of a mile in length and 40 to 50 yards in width. It is irregular or serpentine in outline, with a rustic bridge over its centre, and contains a variety of fine fish, also waterfowl. The margins on both sides are planted with choice shrubs and Conifers, such as *Picea lasiocarpa*, *Pinus Coulterii*, *Abies Douglassii*, a fine specimen of Copper Beech, Chestnuts, &c. A quantity of plants of various species of *Nymphæas* had been recently planted in the lake. The landscape above is diversified with tastefully disposed clumps of trees. The outskirts are belted with young trees, through which is a long walk over a mile in length, on either side of which spring up early in the year quantities of Bluebells, Daffodils, and other welcome spring flowers. The land on this side, about 40 acres or more in extent, is devoted to pasturage.

The kitchen garden is situated to the right of the mansion out of the grounds proper; this is five acres in extent, enclosed in a "ring" fence. This garden possesses two disadvantages—viz., having no walls and a northern aspect. It will thus be seen to be almost impossible to obtain very early crops under such difficulties. Notwithstanding these drawbacks, however, Mr. Fox manages with the exercise of much skill and attention to produce excellent crops of vegetables. The quarters devoted to Beet, Onions, and Peas bore the stamp of good cultivation. Strawberries are grown on a large scale here, *Vicomtesse Hericart de Thury* and *Pioneer* being the principal varieties. The *Asparagus* is grown after the French method, and the extraordinary growth of the plants certainly indicates that this system succeeds well here. Bush fruits as well as Apples and Pears adorn the margins of the walks; trees of the latter were bearing very heavy crops of good fruit.

At the bottom of this garden is a long range of successional Peach houses. The trees are large, healthy, and well trained, and consist of the leading varieties, many of which were bearing fair crops of well-coloured fruit. I ought to note that the houses are "lean-to, and the trees trained on the curvilinear system. Upwards of a thousand Strawberry plants were flourishing in pots for forcing purposes in front of this range. Mr. Fox grows *Pioneer* as the principal variety for forcing, and finds it to succeed far better than the *Vicomtesse de Thury*. Another range of houses consisting of three large vineries, a greenhouse, and stove, are situated at the upper end of the kitchen garden. The Vines having been much neglected previous to Mr. Fox taking charge a year ago, the latter decided to discard

these and replant with new Vines. Advantage is taken of the absence of Vines to grow Pelargoniums and similar plants for producing cut flowers, which are largely in demand. A large collection of Azaleas, white principally, grown for affording cut flowers, occupy the greenhouse. The large stove contains many hundreds of small Palms, Orchids, Ferns, and foliage plants, such as Dieffenbachia Bausei, Dracenas in vars., Crotons, Pandanus, Acalyphas, Caladiums, &c., for furnishing purposes. Two small span-roof houses are devoted to growing a number of young Palms and similar plants for same purpose; also a large quantity of Eucharis, Gardenias, and Stephanotis for supplying cut flowers. Adjacent to the gardener's house—a commodious residence—is a large house devoted exclusively to growing many hundreds of Adiantum cuneatum in pots for supplying fronds for decorative purposes, all in excellent health, and several heated pits for the same class of plants. In conclusion, Mr. Fox is to be congratulated on the excellent order and arrangement of the several departments under his charge.—T. W. SANDERS.

THE ORCHARD.

BARREN FRUIT TREES, AND HOW TO MAKE THEM FRUITFUL.

THERE are many causes to which the sterility of fruit trees in hundreds of orchards in this country may be ascribed. Not the least of these is the result of annual neglect—that is to say, that brought about by leaving the trees year after year to take care of themselves, by failing to make a timely and judicious use of the pruning saw and pruning shears; consequently the overcrowding of tree and branch, excluding sufficient light and air from the branches, prevents to a great extent the formation and development of fruit buds, and encourages the growth of lichens and moss. The operator, being provided with a good pruning saw, pruning shears, and ladders, should begin the work of amputation by cutting out all the cross and ill-placed branches, so as to let plenty of light and air among those left to form the tree, and which, almost needless to say, should be those best furnished with fruit buds and indicating most vigour and health. The upright ones of these should, if necessary, be shortened with the shears. The thinning and shortening of the branches having been completed, the prunings, which in magnitude will in many cases be equal to that of the trees whence they were taken, should be faggotted and then removed to the faggot yard. The moss should then be scraped off the trees with a piece of hoop iron or lath, the trunks and principal branches being afterwards scrubbed with an old besom.

This being done, a cartload of quicklime, more or less according to the number of trees to be operated on, should be taken to the centre of the orchard and dissolved in a large tub or iron tank, adding thereto a small per-centage of new dry soot. The liquid, having been well stirred, should then be strained through a fine sieve into the garden engine, and, choosing a calm day for the operation, be applied forthwith to the lichen-infested branches from every side of the tree, so that they may be completely smeared with the solution. This simple and effectual remedy will speedily destroy the lichens, consequently the trees will become vigorous and fruitful.

The next step that should be taken with a further view of promoting fertility is the laying on between the trees a good surface dressing of whatever fertilising agent can be spared for that purpose. Failing a better one, decomposed vegetable matter will contribute to the object in view, and the substance of which by the agency of the worms will reach the roots in due time. Furthermore, if a trench about 3 feet deep and 2 feet wide be opened at from 3 to 5 feet (according to the size of the tree to be operated on) from the bole, the roots in that space being cut clean away in the process of excavating the soil, the latter with the addition of some richer soil being afterwards replaced in the trench, the result will be such as not only to compensate for the labour involved in the operation, but also to justify an extension of its application in the same direction afterwards—that is, to trees which fail to yield satisfactory crops during favourable seasons.—H. W. WARD, *Longford Castle, Wilts.*

KITCHEN GARDEN.

WITH the advent of the new year many who have done little or nothing in their kitchen gardens during the past two months will now bestir themselves and prepare for getting in the crops in spring on the first favourable opportunity. To do this with advantage the soil and everything should always be in readiness beforehand, and this should be the main work just now in vegetable gardens. Throughout January none can make any mistake by manuring, digging, or trenching all empty quarters. Many autumn and winter vegetables, such as Spinach, Broccoli, and Savoy, are now over, and the sooner the remains of them are cleared off and the ground turned up to the weather the better. Every foot of ground now is ready for the reception of the spring crops, and we have found so many advantages from being thus prepared at

sowing and planting time that we would advise all of our readers to try the system.

Forcing Vegetables.—Plenty of choice vegetables will now be produced, and the great point is to maintain a regular supply after the first have been sent to the table. This is easily done by putting in successional batches of roots or seeds in suitable quantities, and at intervals according to the demand. Those who have not had the means to begin forcing in autumn may do so now with the assurance that they will find it quite easy if the instructions given in previous numbers are followed.

Tomatoes.—These may also be sown now, placing half a dozen seeds in a 3-inch pot, which has been previously filled with a light mixture of loam, leaf soil, and sand. The pots need not be plunged, as the seed will germinate freely and the young plants grow well in a temperature of 70°.

Potatoes.—Where hotbeds have been made up a week or two ago the tubers may now be planted. The soil in which they are placed should be rather rich, and 1 foot from set to set and 18 inches from row to row will be a suitable distance. In planting do not break off any strong growths which may be formed, and as these will soon appear above the soil more protection than the glass light must be given when frost occurs.

Radish.—A little seed may be sown in any corner of the hotbeds, and a patch may also be put in in a sheltered corner at the bottom of a south wall, or in a cold frame or under a handlight.

Rhubarb and Seakale.—These may now be covered with the pots made for this purpose, and if a quantity of leaves and littery manure mixed together is placed over these so as to create a gentle heat the crowns will soon be induced to start into growth, and much fine produce may be secured in this way during the spring.

Seed Lists.—These are coming in, and their contents will no doubt be usefully discussed in the pages of the Journal, and the characters of the different varieties of vegetables estimated for the benefit of the inexperienced.

FRUIT-FORCING.

Cucumbers.—*Plants in Houses.*—Take advantage of every opportunity to make the most of the little sun we are as a rule favoured with at this season, giving a little ventilation if the weather be mild in the early part of the day, and close early in the afternoon, or shortly after noon, damping the house at the same time with tepid liquid manure. On fine mornings the pathways should be damped and the plants lightly syringed overhead, which will to some extent assist in keeping down red spider that is often troublesome where sharp firing has to be resorted to to keep up the required temperature. Weak tepid liquid manure may be given to plants which are making free growth, but should the plants show any signs of not growing tepid water only should be applied until the growth becomes free. To encourage surface roots a top-dressing should be given of turfy loam in a lumpy state and a fourth of horse droppings, having it previously warmed to the same temperature as that of the house. Maintain the night temperature at 65° or a few degrees higher in mild weather, 70° to 75° by day, and 85° to 90° with sun heat, keeping the bottom heat steady at 80°. Plants for the early spring supply of fruit should now be prepared, sowing the seeds singly in 3-inch pots half filled with soil, so as to leave space for top-dressing when required, plunging the pots near the glass in a brisk bottom heat. Seed for raising plants for growing in pits or frames heated by fermenting materials should now be sown, for particulars of which see Melons. Taking free-bearing and constitution into consideration Telegraph is still unrivalled.

Melons.—From seed sown now plants can be raised to afford ripe fruit late in April or early in May in light well-heated houses. Sow the seeds singly in 3-inch pots, leaving room in the pots for top-dressing, and plunge the pots in a bottom heat of 80° to 90° near the glass. As soon as the plants have unfolded the first leaves top-dress them, keeping them as close as possible to the glass without touching so as to prevent a weakly growth. As to varieties tastes differ, but Scarlet Premier and High Cross Hybrid are capital varieties.

Making Hotbeds.—Fermenting material composed of Oak or Beech leaves two parts, to one of stable litter well mixed and thrown into a heap, turned over twice and damped as advised in our last calendar, will now be ready for making up. The most suitable site is a dry one, and in front of a wall or hedge to the north, so as to break the winds from that quarter, and it is well if there be a similar protection to the east and west. The site should be dry, or if not it should be made so by a layer of faggots. The bed should be so formed that it will have about 6 inches of space to spare all round the frame. In making the bed put the materials as evenly together as practicable, and beat them down as the work proceeds. The bed should be made one-third higher than the intended height to allow for settling, and this will need to be about 6 feet high at the back and a foot less in front. The bed will have settled down in about a week, when level the surface of the bed, return the frame, and put in sufficient fermenting material to make the depth at the back of the frame correspond with the front, and over this 4 to 6 inches of sawdust or similar material for plunging the pots in, or pots or cuttings, &c. It is well to have the frame with a cavity inside, which may be made by nailing some laths an inch wide inside vertical to the frame, and 6 inches less than its depth, nailing some half-inch boards to these so as to form the cavity. This will allow of the plants having the benefit of top heat from the linings after that from the bed is declining.

Cherry House.—When the trees are fairly growing let the day temperature be kept at 50° to 55°, and if the days be bright air should be admitted, but only to the extent of keeping the temperature from rising above 65°, keeping it from sun heat at 60° to 65°, admitting a little ventilation in the

first instance at 55°, and when it declines to 55° close the house for the day. Syringe overhead in the morning and again in the afternoon if the weather be bright, but if the weather be dull it will suffice if the borders and other available surfaces are damped whenever they become dry. The night temperature should still be kept at 40° to 45°. See that the borders are thoroughly moistened through, as root-action commences with, if it does not precede, the growth of the stems. The water supplied ought not to be less in temperature than that of the house. Trees in pots will need copious and repeated waterings if the soil has become dry.

PLANT HOUSES.

Dendrobiums.—These are scarcely wanted in flower until *Calanthes* are past their best, and the houses in which they are arranged are still very gay, and will continue to be for some weeks longer. But to succeed these a few *Dendrobiums*, such as *D. Wardianum*, *D. crassinode*, *D. Devonianum*, *D. heterocarpum*, and others that were placed early to rest, should now be thoroughly soaked in tepid water and introduced into a temperature of 55° for a week, and then be given a temperature of 5° higher. If these plants are grown in baskets suspend them from the roof until they come into flower, when they can be taken down and arranged amongst other plants if thought desirable. If they have been properly attended to during their resting period their flower buds will be very prominent along their pseudo-bulbs. Some care will be needed in the supply of moisture to these plants until they start into growth. The atmospheric moisture in an ordinary plant stove will be ample until after the plants have flowered without the use of the syringe. At the root after the first soaking only give sufficient to prevent the moss and peat becoming dry. A few plants of the old and useful *D. nobile* may also be started under the same conditions. Before introducing these sponge the foliage with water in which a little soft soap has been mixed to remove all dust. Those not wanted to come into flower must be kept cool, only giving sufficient water to keep their pseudo-bulbs from shrivelling. The same remarks apply to such varieties as *D. Falconerii*, which must have a good season of rest if it is to be flowered well, *D. primulinum*, *D. Parishii*, *D. crystallinum*, the varieties of *D. Pierardii*, and many others which, if kept at rest for some time longer, will form a good succession to the first varieties mentioned. The small-growing but beautiful *D. pulchellum*, which generally is rather late in completing its growth, should now, if thoroughly ripened, be placed for a month or six weeks in a temperature that will not range above 50°. *D. thysiflorum*, *D. chrysotoxum*, and *D. densiflorum* should not be punished during their resting season by being placed in too low a temperature. The one last named is sufficiently low, for if starved their foliage is rendered of a yellow sickly appearance. The first-mentioned may still be kept at rest, while a plant or two of *D. densiflorum* may be placed in a temperature of 60°, in which it will soon show its flower spikes.

Maxillaria picta.—This amongst sweet-scented Orchids is a gem when grown in 5, 6, and 7-inch pots, in which size it is most useful for decoration, and can be used in light positions in the dwelling-room without injury. By judicious treatment and sufficient plants a supply of flowers can be produced during November, December, and January—the three worst months of the year. While making their growth these plants enjoy the heat and moisture of the warmest house—in fact, the conditions of an ordinary plant-stove suit them well. Directly their growth is finished the plants must be placed in a lower temperature. One end of the house in which *Odontoglossums* are grown will do well, only give them a little more light. These plants can then be introduced into heat as required, and they soon show their flowers at the base of the pseudo-bulbs, and just before they expand they should be placed in a temperature of 50°, in which the flowers last nearly double the length of time they do when kept in a higher temperature. After flowering they are again placed in the coolest structure, in which they will remain for another month to rest; while in this condition only sufficient water is given to keep their pseudo-bulbs and foliage fresh. The plants are divided if they require it, and repotted as soon as they show signs of growth. Good fibry peat, the small particles shaken out, and a little charcoal with a layer of living sphagnum moss on the surface, suit them well. Every alternate year the whole of the old compost is shaken from their roots and fresh supplied. After potting, and until the plants are in active growth, water is carefully applied, and afterwards liberally until growth is completed.

Cypripedium insigne.—This and its varieties are amongst the best *Cypripediums* that can be grown, for they will stand nearly three months in the conservatory while in flower. The majority of our plants have flowered, and are placed in a cool house where the temperature is not allowed to fall below 40°. They will remain in this position for another month, and then be allowed to make their growth in a vinery. A vinery just started suits them admirably—in fact, we very seldom move our plants from this position until they are showing their flowers in early autumn, and then according to the time they are required we assist them to develop in a little more heat.

QUEEN BATTLES.

THOUGH queen battles are not at all uncommon, but of frequent occurrence in large apiaries, they are seldom seen, and therefore a few words anent and descriptive of them may not be

unwelcome to some readers of the Journal. Queen bees are interesting creatures from every point of view. Their fertility is astounding, as well as their labours in distributing their own eggs, for they lay all the eggs of their hives. In appearance they are more genteel than either drones or working bees. In manner they are quiet and inoffensive, modest and retiring, graceful and queenly. They have stings, which are slightly crooked and not half so sharp as those of working bees. Their stings are never used except in royal battles; indeed no amount of annoyance, handling, or squeezing by the fingers of the bee-master can provoke them to draw their swords; in a word, they will bear pressing to death rather than use their stings! How different it is with working bees, which so readily use their stings on receiving the slightest touch; but the quiet conduct of queens is changed in a moment into rage and ferocity on meeting rival queens. Whenever two queens meet they rush at each other furiously and quickly fight it out. Queen battles do not last long, but they are desperate. In all such contests it is death or victory. Reconciliation or compromise is out of the question.

In autumn while swarms are being united spare queens are plentiful. This year I took two young queens into our kitchen and put them in tumbler glasses on the dresser. As there was a lady in the house who had not seen a queen battle the tumblers were lifted and the queens permitted to meet. They had never seen queens before, but these at once rushed furiously at each other and quickly fought it out. One of these queens was a half-bred Ligurian, which gained the advantage at the first grip. It took hold of its rival by the shoulders (thorax) just behind the next, and used its dagger from below in the bosom of the other queen, which struggled hard for a time to use its sting but in vain. She was held fast in the grip of the Ligurian and stung to death in about two minutes, when the victor withdrew her sting and walked away from her victim apparently none the worse for the encounter.

In another queen battle I witnessed there was a violent struggle to get the best hold or mastery, clasping each other round their waists and twirling round and round. In this case the queens were in the act of swarming when they met, both going with the swarm, and met on the flight board. I tore the combatants asunder and cast them in the air amongst the swarm then on full wing. They were hived with the swarm; next morning one of the queens was found dead on the floor board.

Once at Sale I cast two swarms together and left them for a few minutes, and went back to see the battle or the results of it. I was too late, the queens had met amongst the bees as they hung clustering to the crown of the hive, and fell in their struggle to the board below. The victorious queen was just leaving the one she had killed and walked away from it, as I thought, with an air of triumph.

Queen bees come into the world with an undying dislike to each other, and this instinct is manifested in their infancy and as long as they live; indeed before they are born they begin to sound the trumpet note of war, which bee-keepers know and sometimes like to hear. When bees swarm the old queens go with the swarms, and young queens are in royal cells to take their places, or, in other words, to be their successors. The queen that is first matured in any hive (and there are generally from three to six reared in every hive that swarms) heralds her own advent by making the distinct and well-known sounds which have been alluded to. She means to reign. One or more of her sisters come to perfection and at once begin to utter dissentient sounds from their cells, and thus put in their claim to the high position which at birth fell to the lot of the first-born. The sounds, or piping, which come from the cells of her sisters provoke her much and cause her to run up and down the hive with murderous intent, for she wants to kill them all; the bees, however, prevent her from carrying her desires into execution by guarding the cells of the younger queens and warding her off when she comes near them. This happens when the bees mean to swarm, and the piping goes on for three days and nights. When the bees do not wish to swarm they stop the piping and kill the supernumerary queens and cast them out. The reports seen about two queens living together happily in a hive I read with great mistrust, for two queens in a hive are as unnecessary as they are unnatural.

In uniting swarms many bee-keepers are afraid of both queens being killed in such battles. Though it is just possible for both queens to be wounded at the onset of the encounter, it so rarely happens that we have no fear of losing both queens in uniting swarms, and, if both queens are young, we do not spend time in trying to catch one of them to prevent a fight. In a very long experience, covering many hundred instances of swarms united, we have only known one battle of queens in

which both were wounded. One was killed in the encounter, the other died next morning.

We see that queen bees come into the world amid great dangers. More are hatched than are required, and in the nature of things two will not live together and indeed are not permitted to live together. A swarm or a stock of bees refuse to have two queens in a hive. The working bees often prevent queen battles by killing spare and unwelcome queens themselves. They do this work by a wonderful and cruel process. When the bees find a strange or unwelcome queen bee amongst them they seize and enclose her by clustering closely around her—so closely that they appear to be crushing her to death. In these little clusters of about thirty bees the queen is quite hidden from sight. These clusters are termed "regicidal knots," and certainly they are formed by little savage regicides, every one being bent on destroying the queens. But they do not use their stings in this work; if they did the queens would be killed in a few seconds, whereas they seem to torture the queens for hours, it may be for a whole day, by encasing them in these hard regicidal knots. I have saved the lives of many queens by tearing them from the grasp of their savage tormentors.

If young queens safely pass through the perils of their infant days, and are happily placed at the head of a swarm or colony, they have then to expose themselves by taking necessary excursions to the fields. When queens are about five or six days old they leave their hives to meet the drones; and these excursions are not unattended with danger of loss of life, for many never return, how they are lost no one can tell. Those that meet drones and safely return never leave their hives again but on occasions of swarming.—A. PETTIGREW, *Bowdon*.

THE COMING BEE.

THE remarks on this bee by Mr. Stewart read very "American" to me, and I am glad that our good friend Mr. Pettigrew has issued his note of warning. We are most of us disposed by nature to discard what is old and trust to the new; in this respect we are still like the Athenians of old. But to what have the efforts of the Bee-Keepers' Association been directed but the encouragement of bee-keeping among the cottager class? Now with all our lectures, and leaflets, and advice, it will yet be years before there will be any general conversion of the cottager to the bar-frame hive. I think this may be reckoned an ascertained fact. There is far more hope of inducing them to try sectional supers on flat-topped straw skeps, such, for instance, as the Buttermere skep. Neither do I think that artificial swarming will be generally adopted yet awhile by the cottager. Now, then, supposing the excessive cultivation of wing power in the queen, would it be an advantage? Several years ago, when living in another county, a cottager's bees in my neighbourhood were always noted for swarming "right away." They went long distances and were often lost. At the end of last season I had mixed two hives of condemned bees with a favourite stock. These bees worked through a glass passage into a spare room. Friends in my house, interested in my manoeuvres, watched them frequently the following day. On my return home I learnt that three queens had been seen taken along the passage dead! This news was decidedly unsatisfactory. Several examinations detected neither queen nor eggs. The season was getting on. What should I do? I bought for a trifle a weak stock from a cottager, drove it with difficulty, there were not more than a large double handful of bees. Fearing that the weather was too cold for opening the entire hive and spraying with scented syrup, I placed in rear of the stock a queen-excluder bar with double zinc, so as to lessen the size of holes, put a bar of honey behind this, threw in my driven bees, and then added the dummy and closed the hive. In this state I left them ten days or a fortnight; then one evening I removed the queen-excluder bar, and the following morning a good handful of dead bees were in the passage. My plan had been, I considered, partially successful, and I hoped that many bees with the queen were accepted.

In the spring her majesty was discovered, and a most valuable bee she proved for breeding purposes. This hive was decidedly my most populous and my best working hive. From it I obtained over 50 lbs. of sectional and super honey, the former from the rear. One day when the bars in the super were nearly all sealed there was a manifest diminution in the number of inhabitants—the super was, in fact, nearly bee-less. I was convinced a swarm had escaped. I gained no tidings of it, but many weeks after a neighbouring bee-keeper told me he had seen a large swarm go "right away" over the town. Was it mine? About ten days later ditto repeated. On each occasion nothing was seen of the swarm, although the window where they work is being continually passed by members of my household. On inquiry at my friend, the cottager, I find his swarms have a knack of getting away!

Here, then, in two cases, either by selection or survival of fittest, certain queens appear to have acquired a greater power of flight, but where is the advantage? To me it appears, on the contrary, a dead loss. If our ordinary bees in summer can fly easily at the rate of a mile in a minute (and this I apprehend they do), surely this is sufficient wing power, and scarcely needs increasing. What we require are healthy

queens, but provided their early flights are sufficient for impregnation—and then the slim and genteel appearance of the virgin queen renders flight more easy—what further flight is requisite? Nay, supposing artificial swarming to be regularly practised, the queen would never fly again after impregnation. Why, then, strive to increase her powers of flight? and supposing the attempt made as Mr. Stewart suggests by trotting out his queens, a proceeding, as Mr. Pettigrew shows, most likely to end in her loss, would half a dozen flights materially improve her powers? I trow not, and if the "coming bee" is to be noted for extra flying powers in the queen I should vote for the old, believing that if a queen's power of flight were greatly increased, instead of being the "coming bee," she would be more frequently the "going, going, gone!"

No, it is not all bees that are so well educated as the old woman's, who told an inquirer that her John always managed the swarms. "Aye," was the reply; "what do you do when John is out of the way?" "Oh! well," she retorted, "her bees never did swarm when John was out of the way!" But even if this education of the bee is complete will John be always able to fly after the swarm? If not, I almost think our cottagers will be content with present powers; and this much is certain, that if they will bestow a little more care and attention on their stocks, and, though still sticking to their straw skeps, try some of the sectional appliances, and not slaughter in the autumn, the present brown bee or some of the hybrids tolerably common now will help, in favourable seasons, to pay their rent and provide some fire for the winter.—Y. B. A. Z.

[ERRATUM.—A printer's error occurred on page 519 of our last issue on the eighth line below the diagram. For "if food is" read "if brood is," and the matter will be understood.]

TRADE CATALOGUES RECEIVED.

- W. Piercy, 89, West Road, Forest Hill, London, S.E.—*List of Summer-flowering Chrysanthemums*.
Hooper & Co., Covent Garden, London.—*List of Novelties for 1884*.
Frederick Roemer, Quedlenburg, Germany.—*Catalogue of Flower, Vegetable, and Agricultural Seeds*.
B. S. Williams, Upper Holloway, London, N.—*Catalogue of Flower and Vegetable Seeds*.
Dickson & Robinson, 12, Old Millgate, Manchester.—*Catalogue of Vegetable and Flower Seeds*.
George Bunyard & Co., Maidstone.—*Catalogue of Vegetable and Flower Seeds*.
Dickson, Brown & Tait, 43 & 45, Corporation Street, Manchester.—*Catalogue of Vegetable and Flower Seeds*.
Robert Veitch & Sons, 54, High Street, Exeter.—*Catalogue of Vegetable and Flower Seeds*.
Sutton & Sons, Reading.—*Amateurs' Guide in Horticulture, 1884 (Illustrated) and Pocket Garden Calendar*.
Chas. Sharpe & Co., Sleaford.—*Catalogue of Flower and Vegetable Seeds (Illustrated)*.
Wm. Leighton, 89, Union Street, Glasgow.—*Catalogue of Vegetable and Flower Seeds*.
Francis and Arthur Dickson & Son, 106, Eastgate Street, Chester.—*Catalogue of Vegetable and Flower Seeds*.
Ralph Crossling, Penarth Nurseries, South Wales.—*Catalogue of Vegetable and Flower Seeds*.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (G. B.).—Nesbit's "Practical Land Surveying" and "Practical Mensuration," both published by Longmans, Green & Co., are reliable works upon these subjects. Colenso's "Elements of Algebra," published by the above firm, and Gill's "School of Art Geometry," are both useful elementary works. The last can be obtained through any bookseller.

Gardeners' Year-Book (*Young Gardener*).—This work is in the press and will be published in a few days.

Renton's Monarch Leek (*J. A. W.*).—No doubt many persons besides yourself would be glad to grow this variety. We are not able to say where seed is to be had, but if there is any for sale it will presumably be advertised.

Vines Unhealthy (*A Lady*).—We have seldom seen Vine wood so unsatisfactory. It is soft, immature, and contains by far too much pith. Either the border is defective or the foliage has been overcrowded, and possibly also the Vines have been overcropped. Without knowing the state of the border and roots, the age and distances apart of the Vines, and of the laterals on the rods, we cannot give you any useful advice on the matter.

Plum Suckers and Seedlings (*J. E. W.*).—The seedlings may be fruited if you choose to ascertain if one or two of them may perchance afford you new and good varieties, but there is small chance of either the suckers or seedlings bearing fruit of any substantial value. We should regard them as stocks, to be grafted or budded, the latter being the best method of increase.

Trenching and Planting (*H. P., Winchester*).—It would be a mistake to trench deeply such soil as yours, and bring up a great quantity of clay. After trenching the soil should be allowed to settle, but not necessarily "for months." The subject will be referred to in our "Work for the Week" columns in an early issue.

Cactuses (*E. Adams*).—We shall shortly publish notes on the culture of these plants, with other particulars such as you appear to require, and possibly they will be of more service to you than anything to which we can refer you in the manner you suggest.

Making a Tennis Ground (*J. B.*).—If the ground is wet and spongy it ought to be drained, and a layer of ashes 2 or 3 inches thick covered with an inch of very sandy soil would render the surface firm and porous. If the site is naturally dry the ashes will not be advantageous, but rather the reverse, as the grass would be the sooner parched and browned in dry weather.

Covering Mushroom Beds (*Cambrian*).—Equally good crops are had in houses and sheds when the beds are covered with hay in some cases and short straw in others. Straw shaken from the manure is preferred by growers of Mushrooms in the open air, and there can be no better material for beds under cover. Mr. Barter's address is given on the first page of "Mushrooms for the Million," and you can procure the information you need by writing to him.

Wellingtonias Coning (*L. F. Moffat*).—Many trees have produced cones in this country. At Orton Hall, near Peterborough, there are thousands of them, and seed has been gathered and sown; but no seedlings have been raised, or at least had not been a few months ago. We believe, however, that Wellingtonias have been raised from English-grown seed. The example you have sent is very fine, the cones, we think, being among the largest that have come under our notice.

Apple Tree Cankered (*F. J.*).—The specimen you have sent demonstrates that your tree is seriously affected with canker. In this case the disease has certainly not been caused by insects, but is the result primarily of immature wood. Are not the roots of the tree in wet or ungenial soil? We suspect they are, as the portion sent indicates that the tree has made long soft growths. Draining, root-lifting, and the addition of calcareous matter appear to be needed. Scrape the parts affected with American blight, and follow the treatment generally described by Mr. Iggulden in pp. 550, 551, last week.

Chrysanthemum Flower Defective (*R. C.*).—You ask "If the treatment has anything to do with the incurving of the florets of Princess of Teck?" It has everything to do with it, and the flower you have sent is not half developed because it has only been half supported. Early disbudding and adequate support afforded by careful watering, rich top-dressings, and supplies of liquid manure as needed, are the essentials for producing well-developed blooms. Some of them are then finished by dressing, an art that can only be learned by experience.

Murray's Vine Composition (*J. D., and others*).—You will find this insecticide advertised in another column. It is prepared by Mr. G. Murray, gardener, West Ashby Manor, Horncastle, and the majority of commendatory letters that have been published have been written by gardeners in Lincolnshire, where the article appears to have been extensively tried and given satisfaction.

Removing Garden Structures (*R. S. J.*).—A nurseryman who erects greenhouses solely for the purpose of conducting his business can remove them if he chooses to do so, as they are part of his stock in trade, and the fact of their being on brickwork does not abrogate his right in this respect. He is entitled to whatever compensation he can obtain if the structures are not removed on the expiration of a lease. This answer only applies to *bonâ fide* nurserymen and florists, not to persons who grow plants for pleasure and sell a number from time to time to assist in defraying expenses.

Cleaning Gourd Seed (*J. W. H.*).—Take out the pulp containing the seeds and place it in water, letting it remain for a time, then rub it well with the fingers in the water, separating the seeds. Remove the matter, and in fresh water proceed as before, and eventually the partially cleaned seeds may be placed in a hair sieve, immersed in water, and the cleaning process completed, when they can be spread out and dried. We are glad your Vines are now promising well. No subject is too "trifling" for our attention provided we can impart information that may be useful to inquirers.

Species of Cyclamen (*Old Subscriber*).—Cyclamen persicum is a native of Cyprus and other parts of the East, and was introduced in 1731. Many varieties have been raised from it, and amongst them is *C. giganteum*, a form distinguished by its larger flowers and stronger growth. *C. hederifolium*, *C. europæum*, *C. latifolium*, *C. neapolitanum*, and *C. vernum*, are all natives of Europe, and are quite distinct from *C. persicum*. They are hardy, and have a pretty appearance on a rockery.

Vine Management (*J. C.*).—You are perfectly right in your views. Nutrient is stored in Vines by the agency of the leaves, and this important process cannot be satisfactorily accomplished if the leaves have not space for development by full exposure to light and air, nor if they are permitted to become infested with red spider or thrips. Overcrowding of the foliage and a want of cleanliness are among the chief causes of failures in Grape culture. We shall be glad to have your notes when you find it convenient to send them.

Birds and Fruit Buds (*C. J.*).—A mixture of lime and soot applied to your Cherry trees with a syringe or water-engine would not be injurious to the buds, and might possibly act as a bird-deterrent. We have found that freely dusting Gooseberry bushes with lime when the branches are wet with dew is not at all liked by birds; whether they object to the white colour or not we are unable to say, but we know that bushes so dressed have not been visited by birds, while others left undressed have been deprived of most of their buds. We found that lime similarly applied to Plum trees for destroying moss on the branches also prevented birds visiting the trees. If it is the colour of the whitened trees that keeps off the birds then the addition of soot would not be an advantage. You might try the lime alone and in mixture with soot, and note the results.

Introduction of Primula sinensis (*Hants Subscriber*).—We presume you allude to the above plant, of which so many forms adorn our greenhouses and conservatories in winter. As its specific name implies it is a native of China. Mr. John Reeves, who died at Clapham in 1856, first directed attention to this plant. He was a tea-taster to the East India Company, and resided in China for many years. In 1821 the Chinese Primula, in consequence of his sending a drawing of it, was introduced by Captain R. Rowes, and presented by him to his relative, Mr. Carey Palmer, of Bromley, Kent. Mr. Reeves commenced sending plants from China in 1816, and besides sending twelve new Chrysanthemums in 1820 he sent the double Chinese Cherry, *Prunus serrulata*, and the Chinese Plum, *Prunus salicina*, to the Horticultural Society in 1820.

Heating (*J. T. S.*).—Provided the level of the water in the supply box is half an inch lower than the highest point of the pipes, the circulation, all other matters being right, will be perfect. The supply box may be higher, but as you ask for the minimum height we have given you a reply that you may act on with safety. Two soot doors are usually employed for a saddle boiler, but if set, as it ought to be, with what is termed a "split" draught—which directs the fire from the back to the front along the outside of the boiler, thence over the crown and into the flue—a central soot door is an advantage. The boiler should be raised on firebricks above the bars, so that when the scraper is used in cleaning it passes easily under the return pipes to the boiler. This is important. Your last question cannot be answered categorically, as everything depends on the setting of the boiler and the correct position of the pipes. You may make your own calculation on the basis that a square foot of boiler surface exposed to the direct action of the fire will heat 40 feet of 4-inch piping. You must remember, however, that the heat passing over the boiler is not half so effective, perhaps about one-third, of that passing under the dome. You would perhaps find useful information in Mr. Fawke's manual on hot-water heating, which can be had from this office in return for 1s. 2d. in postage stamps.

Samples of Vine Wood (*N. J.*).—The Muscat of Alexandria growth is of good average quality, being moderately strong, firm, matured, with little pith and good buds. The cane may be left a length of 6 feet, taking care to insure the lower buds breaking freely, syringing occasionally, and if requisite training the cane in a horizontal position. The Black Hamburgh wood is also in condition to bear good Grapes, but being weaker than the others not more than 4 feet should be left. The Alnwick Seedling rod we should shorten quite to the base of the rafter if not below it, and the pruning of all should be done at once. Do not attempt to crop heavily next year, and permit no crowding of the foliage. There is no doubt that under ordinary circumstances that Vines make considerable growth before there is any root-extension; but, as in your experiment, when placed in bottom heat root-movement commences with the swelling of the buds. We are glad to hear of your success and that our advice has been useful.

Packing Roses and Deciduous Shrubs for Tasmania (*A Fifteen-years Subscriber*).—The present time is the most suitable for dispatching such plants on their voyage as they would travel well now and arrive at their destination at a convenient time for planting. Strong wooden boxes should be obtained for the purpose, and could be readily made by a carpenter of any requisite size. The roots of the plants should be surrounded by soil, clay, and moss, and bound securely with matting. They can then be placed in rows either along the bottom or sides of the box, each row being secured in position by a batten nailed to the side or bottom of the box. They are thus rendered practically immovable. Thoroughly moisten the soil, but allow all that is superfluous to escape before screwing the lid on. A few holes may be bored in the sides, but these should be protected with large and strong pieces of perforated zinc, or rats may prove very injurious. The case when complete must have the directions painted legibly upon it, also with the request that it be placed in a cool portion of the hold, and the plants will need no attention whatever during the voyage. We heard recently of a consignment of Roses sent in this manner to Australia, which arrived in excellent condition. You will, we presume, send them by steamer and not by a sailing ship.

Arranging Pipes (*Rosa*).—In consequence of the great numbers of letters we receive pertaining to such a diversity of subjects it is next to impossible for us to keep in mind the particulars of a case conveyed in a former letter, and as it is our practice to destroy questions as soon as they are answered we have nothing to refer to. You ask "how many through pipes for steam" you should have? We presume you mean pipes with troughs on them for holding water. So far as we remember your case one would be ample, and even it would not need to have water in it always, as quite sufficient moisture would be provided by syringing the house and damping the walls and paths. The pipes will do very well placed side by side, the flow rising gently from the return falling steadily to the boiler. If the incline is very great a continuous evaporating trough the entire length would obviously be of little use, and it would be better to have some moveable zinc troughs about 4 feet long, for fixing on the pipes when and where required. The pipes may be

fixed 3 or 4 inches below the grating, and with sufficient heating surface which, though involving a little extra outlay in pipes, is in the end always economical owing to the saving of fuel, the path would never be too hot for walking over. If there is a possibility of water rising in the stovehole you may have the pipes almost close to the grating, while if the danger is imminent you had better, perhaps, consult a competent person who has had experience in heating with pipes below the boiler. We know of a nursery where much of the piping is so arranged, and the entire system works smoothly and satisfactorily. We, however, do not advise its adoption except in a case of necessity.

Climbers for Conservatory (*N. S., Beckenham*).—Presuming the house is lofty and you desire plants to cover roof space quickly and produce pendent sprays of flowers, you will find the following suitable—*Tacsonia Van-Volxemi* and *T. exoniensis*, *Passiflora rubra racemosa* and *P. Empress Eugénie*, with *Cobæa scandens variegata*. A little less vigorous, but not less beautiful, are *Clematis indivisa*, *Rhodochiton volubile*, *Mandevilla suaveolens*, red and white *Lapagerias*, *Lonicera sempervirens*, and *Cestrum aurantiacum*. Effective for pillars are *Bougainvillea glabra*, *Habrothamnus fascicularis*, *Rhynchospermum jasminoides* and *Solanum jasminoides*. *Swainsonia Osborni* requires a light position, and is dwarf in comparison with many of the others. It is never easy to answer a question of this kind satisfactorily without some information relative to the height of the house and the number of plants required. We cannot usefully recommend many plants for a wall without knowing its height, also its length, or the number of plants it will accommodate. If the wall is inside a conservatory in which the roof is to be heavily festooned with climbers, few flowering plants will succeed, owing to the absence of light, and the best would be *Camellias*. An evergreen surface without flowers is afforded by *Ficus repens*. Roses suitable for a lofty corridor such as you describe are *Gloire de Dijon*, *Reine Marie Henriette*, *Maréchal Niel*, and *Cheshunt Hybrid*. You had better confine the roots of tender plants to an inside border. We are quite willing to refer to the subject again if you need further information and will supply us with the particulars suggested.

Names of Plants (*P. C. Thorne*).—The plant is *Solanum jasminoides*, a South American species, which was introduced about 1838. An engraving of a flowering shoot, with full description, was given in this Journal, No. 945, May 8th, 1879, page 345. The number can be had from this office post free for 3½d. in stamps.

COVENT GARDEN MARKET.—JANUARY 2ND.

OUR market has been quiet since the holidays, but prices all round have been firmer. The supply of hothouse Grapes has fallen off somewhat.

A RETROSPECT OF THE HOME FARM FOR 1883.

ACCORDING to custom the home farmer's agricultural year begins on October 1st, therefore our observations will commence with the month of October, 1882. In this instance it was quite an unusual period, especially for Wheat-sowing; in fact, after the 20th of October and the great storm which occurred about that time, and until the 20th of February following, it may fairly be said that there was no Wheat season or seed time on strong and flat lying soils. The heavy rains and floods continued almost without intermission until the date above-named in all parts of the kingdom, but more especially in the western and north-western counties. All the Wheat sown after October 20th suffered more or less from a deficiency in plant, and to such an extent that we have no exact parallel for more than fifty years.

But the nearest approach to the difficulties of our seed time for Wheat occurred in the year 1841. There was, however, this difference, that the heavy rains commenced in and through the month of September, and continued until December 14th following, with only intervals of a day or two of fine weather. In consequence of the deficiency of plant large areas were ploughed up after the seed time in January, 1883, and in some instances resown with Wheat, which generally gave but a poor yield of grain. Upon referring to the reports from various districts of the kingdom we find that more than 6½ inches of rain fell in October, 1882, which is double an average fall; also in the following months, including February, the fall of rain was considerably over the average.

It is interesting to trace the weather and its effect upon the Wheat crop from that time up to the harvest. Our record shows that the months of March and down to June inclusive were of a dry but cold character, but the end of June and July was wet and the Wheat suffered accordingly. Fortunately the early part of the month of August in the southern and south-eastern counties was both dry and hot, and to this circumstance we owe the good quality of our Wheat, which is noticed as being very bright and heavy in weight wherever it was harvested in good condition, but the northern and north-midland districts suffered much from the continuous rains which followed, and serious losses occurred in various districts. It is generally thought that the reports of the crop given in on the edge of harvest were, and may be accepted as near the truth as possible. In summing up the reports it must, however, be remembered that the general results were Wheat under the average; Barley, average, but of doubtful quality; Oats, the crop of the season, over average and of good quality; Beans and Peas both over the average; Rye, Vetches, &c., have also yielded well.

The seed time for all the green and catch crops, whether required for feeding or soiling cattle, was favourable, it being concluded before the rains commenced, which destroyed the seed time for Wheat; but the spring months being dry made it favourable for feeding sheep on the land. The crops of Clover and field grasses were under an average. The same may be said of the pastures and parklands, the only exception being irrigated meadows. The haying season was, however, very tiresome and disappointing, and, excepting in a few instances, the hay crop was more or less damaged throughout the western and midland districts. Owing to the forcing rains of July, however, the second growth, whether for hay, feeding, or ploughing, proved abundant. The fine weather in August also proved favourable, and much second growth of hay was made in better condition than the first cutting.

Reports of the root crops, whether Mangolds, Carrots, or Turnips, also of Cabbages and Kales, in general concur in representing them as a good average, although in some of the northern counties and Scotland, where the seedtime is earlier, it was rather prejudiced by the dry weather having continued too long for the benefit of the young plants. The growth of Potatoes, both early and late, has been most abundant and the tubers of fine quality, and it has been quite the exception to find that the disease has injured the produce.

All the green and catch crops have proved most abundant, as also the grass in the meadows and parklands, also on the chalk and limestone hills, which has turned out very favourably for the breeding flocks of sheep. The evidence on this is suggested by the high range of prices at which sheep sold at all autumn and summer fairs, and such a value as will have left but little profit to the vale farmers who purchase them for winter-fattening on the dry and mixed soils of the southern, home, and eastern counties. The abundance of grass in the pastures of nearly every district in the kingdom has also made the demand for cows and calves unusually great, and they were dear and scarce in consequence, and had not the hateful scourge of foot-and-mouth disease interfered with the dairy farmer's projects, the produce of dairies would have been far beyond the usual average.

The milk trade has been good all the summer, particularly in those cases where the farms and pastures are situated near towns and railway stations. The same applies to butter-making dairies, for these have paid well, and perhaps better than by the sale of milk, especially in those cases where the butter makers thoroughly understand the making, and have also the advantage of the late improvements in machinery and implements necessary and connected with the best process of making up the butter. This part of the subject is very important to the home farmer, particularly in pasture districts, or even on arable farms favourable for the production of green crops, roots, and ensilage. A well-managed suckling dairy is the most profitable of all the

dairy practices upon farms distant from towns where the sale of milk and butter is not convenient. The home farmer should remember that the labour bill is at present the greatest obstacle in all parts of the farming business; now with a dairy of good milking Shorthorn cows, with calves well selected for suckling, will prove more profitable than any other system of using dairy produce upon outlying farms. When well managed the labour is very little, and the cows will last longer in milk than they do either in butter-making or milk-selling, owing to the careless manner in which hand-milking is frequently carried out.

The selection of calves is of importance, and it is from the southern and western counties from which they should be obtained, for our own experience has taught us that Devon calves are the best for quality and light weights for veal. The Herefords and Sussex calves are the best for general profit and heavy weights, but the Shorthorns are beneath those named for quality. We advise the breeding and rearing of all the horned cattle required upon the farm as the best security against the foot-and-mouth disease, for in case the dairies are made up by the purchase of animals at the local markets it is extremely difficult to avoid contagion whilst this disease is rife in the country. When, however, all the cattle for milking or butter-making dairies are bred on the estate, and intruders of different callings are forbidden approach to the yards and premises, the disease will be generally avoided. To illustrate the truth of these observations the reports state that at present the counties of Cornwall and Devon are free from this disease, whereas the eastern counties are seriously affected; the former being for the most part breeding districts, and the latter, where mixed or arable farming prevails, the cattle are often obtained by purchase from distant parts and largely from Irish importations. We may here caution the home farmer not to believe the various stories about this disease being spontaneous or even epidemic, for in every instance it is due to contagion, although it is so subtle that the cause cannot in every instance be traced to its true source. It is correct to assume that after all our serious losses and experience contagion is the only means by which this disease can be propagated.

Tillage and cropping on the home farm, as well as the management of pasture and parklands, have received particular attention in this Journal during the past three years under various headings, including "Stock-farming" and "Manuring by Ploughing-in Green Crops." We will, to support our experience and practice, refer to the observations of Mr. Clare S. Read, late member for Norfolk, who said at the meeting of the London Farmers' Club lately: "What my friend Mr. Carington Smith may say about the advantages derived from turning arable land to grass in Staffordshire, I have not the slightest doubt myself that if an acre of land is put down to grass in any of the East Anglian counties that we should lose the production of corn now it is under the plough, and we should not at any rate get any more but rather less meat from it than we do at the present moment; therefore, one of the great things to do to increase the number of stock in the kingdom would be, if possible, to make arable land pay better than it does now. That, I am afraid, is rather a difficult matter."

Here we must observe it has been our endeavour for several years past, by alterations and combinations of systems on every opportunity, to show in this Journal and to illustrate some of the points worth the serious attention of the home farmer. The reporter of Hampshire farming states:—"Depression in agriculture still prevails, and has been caused to a great extent by adverse seasons; but the leading rent-paying crops after all are Wheat, Barley, Oats, and other sale crops according to the soil. Large crops are therefore a necessity both in acreage and acreable produce, and form the chief point worth the attention of the home farmer. When we consider that rent, tithes, and rates are comparatively fixed charges, and will be best met in the future by increased acreages of sale crops, it makes all the difference whether only half the tillage land is cropped or extended to two-thirds, for the fixed charges are the same in either case. Again, it is worth inquiry what real gain the sheep contribute to the farm; for although they are said in some cases to pay the rent, let it be fairly calculated what remains as a commercial profit after having charged interest on the large capital employed and the heavy charges of labour directly and indirectly attendant upon sheep-farming. It ought further to be considered that large outlays in feeding materials are made where sheep are said to pay the rent, accompanied by a reduced acreage of the rent-paying crops, delays of seed time, extra tillage required, the losses of stock which cannot always be controlled, and finally the consumed, or commercially speaking sold to the stock even at a very low price, nothing is left but the manure on the land, and after estimating this, in a comparison

with other systems of cropping, it shows that we can obtain or buy manure cheaper than the sheep can make it. In conclusion, it is by comparison only that just estimates of anything can be made, let it be made between sheep-farming and ploughing-in green crops as manure for the production of corn and other sale crops."

It must be admitted that these are practical remarks worth attention both by the landowner and home farmer. If we notice in almost every district sheep-farming is almost entirely pursued by men of capital who are fond of the pursuit, in fact frequently make it a hobby and are prepared to lose or win by it. The home farmer must, however, be prepared to preface his accounts by a good system, and submit them with a good balance of profits.

Much stress has been laid upon the subject of stock *versus* corn, as it has been fashionable during agricultural depression to assert boldly that corn does not pay, and that stock only is worth the attention of the farmer. Sir J. B. Lawes in a letter to the *Times* a short while ago, under the heading of "Modern Farming," says—"So certain was I that corn-growing as the main source of profit in farming could no longer be depended upon, that about ten years ago I began to lay down my arable land in permanent pasture, and at the present time one-half of my farm is grass." Farther on he says—"Stock, however, as the main element of farming, requires a large amount of capital; corn can be grown by means of artificial manures with very little capital. Granted that stock-farming is profitable, exclusive of the risk of disease, what is the value of that risk? I should be very sorry to advise any young man who had a few thousand pounds in his possession to embark in farming. I should say to him, You cannot farm profitably without stock, and some disease, which all your precautions cannot prevent, may cripple your resources at any moment."

In thinking over these first observations we are struck forcibly with the assumptions contained in them without any practical comparison being made to support them, not even by calling attention to the fact that all or even a large portion of arable land cannot be made into good permanent pasture, Mr. C. S. Read's statement to wit. In the other observations he says that so large an amount of capital is required that the risk of stock-keeping is too great. Now this is a strong corroboration of our opinions; but he makes no comparisons to justify the different conclusions at which he arrives by assuming that corn-growing cannot be made to pay, and therefore encouraging the fashionable delusion which prevails. Our objections refer principally to sheep-farming and the folly of laying land into grass not possessing sufficient staple for its success. We quite believe that, setting the foot-and-mouth disease aside, cattle may be made profitable upon ordinary park or pasture land by dairy cows kept either for milking, or butter-making, or suckling purposes; also that upon rich grazing land bullocks can be fed with advantage, but under any circumstances it is safer to breed the whole of the stock required on the farm.

In conclusion we are aware of the great intelligence, industry, and perseverance required by the home farmer to successfully grapple with all the difficulties of the times and circumstances of soil and climate by which he is surrounded; and in the absence of any specific calculation supporting the opinions in all their variety as given by different authorities which if attempted will prove unreliable, because it is practically impossible to make comparison in figures.

CROTONS.

UNDER the name of Crotons we have a number of plants which must be familiar to everyone connected with horticulture, since their cultivation has become universal. Crotons are included in the natural order Euphorbiaceæ or Spurge-worts, and in horticulture they form a very important section of the class termed "Ornamental Foliage Plants." Perhaps the greatest proof—if proof were wanting—of the beauty of these plants and their sterling worth is to be found in the extraordinary manner in which, during the last few years, they have been developed; for whereas about fifteen years ago only about half a dozen were in cultivation, now upwards of a hundred can be enumerated, and it should be borne in mind that this great increase of variety is not the result of a selection from a batch of seedlings, as is the case with Gloxinias and Begonias, but by far the greater number have been introduced into this country from their native habitats.

Most of the varieties are natives of the South Sea Islands, a few come from the East Indies and Jamaica, while lately several have been imported from New Guinea and Borneo. The remainder are garden hybrids, the result of the handiwork of the horticulturist. It is worthy of note that these latter hybrids are in no way inferior to those introduced from abroad—in fact, it is a matter of opinion whether the variety known as Queen Victoria, which was raised at the Victoria and Paradise Nurseries, Upper Holloway, London, and was the first garden hybrid, is not the best variety in cultivation. Certainly Her Majesty is very popular, and deservedly so. Crotons, then, during the last few years have grown so much in favour generally, and so many varieties of different character and various degrees of excellence have been introduced to cultivation, that they are now regarded as indispensable to the exhibitor and horticultural decorator. These plants present a beautiful combination of colour and elegance such as is not to be found in any other class of plants, and if we require proof of this I need only remark that there is scarcely a horticultural show throughout the country where Crotons do not hold an important position. It does not matter whether it be in the class for a given number of fine-foliage plants, or a given number of foliage and flowering plants, or in the class for table plants, or in groups of plants arranged for effect, in each of these cases they are found to be so thoroughly effective as to render it entirely out of the question to do without them.

Three sizes of plants are required for the above purposes—viz., large specimen, medium, and small, and these three sizes will be found suitable for almost all decorative purposes for which tender plants are available. Presuming, then, that Crotons are of so much value for exhibition and decoration, a few remarks on their general culture may not be altogether out of place. Crotons being natives of hot countries, it will be apparent that they require the temperature of a stove to grow them satisfactorily; but it is not

well to keep them in too strong heat. I find that 65° by night and 70° by day, allowing the temperature to rise 10° or 15° by sun heat, with plenty of moisture in the house, suits them admirably. They should be syringed twice a day during the spring and summer to keep down red spider, and slightly shaded from the sun for four or five hours in the hottest part of the day during the months of June, July, and August. When it is not possible to devote a house to them entirely they should be placed together in a light part of the stove and as close to the glass as possible to insure their colouring well. I have heard it remarked that Crotons require starving to bring out their colours properly, but this is altogether a mistake. I am no advocate for starving, and if the term is admissible in gardening at all it certainly should not come under the head of "Cultivation of Crotons." So far, then, from starving Crotons I recommend growing them in a rich compost, and I find the following suits them well:—Two parts good fibrous loam, one part best Hampshire peat, and one part well-decomposed leaf mould, with a little silver sand to keep the soil open, and the addition of a small quantity of Clay's fertiliser, say in the proportion of a 5½-inch potful to a wheelbarrow load of the compost.

Assuming that we have the proper soil and accommodation for cultivating these plants, we will begin with their propagation. Crotons are propagated from cuttings, which strike freely at almost any season of the year; but perhaps the best time is in the autumn and winter, when the wood is matured and growth less free. Cuttings inserted in sandy soil singly in thumb pots and plunged in bottom heat of about 80° to 85°, and covered with a bellglass or handlight, will generally root in about three or four weeks, and as soon as rooted should be gradually exposed to the temperature of the ordinary house. When the pots are filled with roots the young plants should be shifted into 4-inch pots and plunged into a gentle bottom heat, but without being covered with bellglass or handlight, and in a fortnight or three weeks we shall have healthy little plants well established.

Now comes the question, For what purpose are the plants intended? Are they required for large specimen plants for competition, or medium-size plants for general decoration, or small table plants? It will be imperative to decide these questions and to cultivate accordingly; for, although the same temperature and soil will suit in either case, yet the treatment in some details will differ very essentially. We will suppose, then, for our first example that large specimen plants are required, and will select Baroness James de Rothschild, a variety of the broad leaf section, and Disraeli, a variety of the trilobe section. Both of these are robust growers and well adapted for specimens, yet requiring different treatment in some respects from such varieties as Hawkeri and interruptus aureus of the medium and narrow-leaf sections.

Having clean healthy plants, and supposing it to be the month of February, they should be shifted into 6-inch pots, and as soon as they have each about six leaves the points of the shoots should be pinched out to induce them to produce side shoots. When these have grown a good length, and the pots have become full of roots, which will be in about two months, shift the plants again into 9-inch pots, and when they are well established in these the points should be again pinched out to induce more breaks. As soon as these pots are filled with roots, which will be in about two months, the plants should be transferred into 12-inch pots, and, if necessary, the points of the shoots may be again pinched; but if there are about a dozen shoots no more pinching will be required, as this number will be sufficient to form the basis of a specimen plant.

The object now is to induce strong healthy growth and large leaves, which I venture to say are more effective and desirable than a multitude of small shoots, and, consequently, small leaves. The plants should be kept growing steadily through the autumn and winter, and the shoots tied out

and trained into position, and about the month of March should have another shift, this time into 16-inch pots. The plants should be allowed to grow on naturally, and by the autumn we shall have healthy, vigorous, well-coloured half-specimen plants. It may now be advisable to give the plants a top-dressing of rich soil to assist them through the winter, and in the following spring they should have what I shall term their "final shift"—viz., into 18-inch pots, and if the plants have been grown on without a check by July or August they will be 6 feet to 7 feet high and 5 feet through, and ready to take their place in the exhibition. This process will take about two and a half years.

I have chosen the broad-leaved varieties for my examples, as they are more difficult to grow into large specimens than many of the narrow-leaved varieties; but, if treated in the way indicated, they make specimens in much less time than the narrow-leaved forms, such as *Warreni* and *interruptus aureus*. These should have the same treatment generally, but they will not require potting so soon in succession, nor will they want pinching, as they branch freely and make more handsome plants if allowed to grow naturally.

Having said so much on large specimens, I will now offer a few remarks on medium-size plants. Let us suppose, then, that we have healthy plants in 4-inch pots, as in our first example, and the season is the month of February; they should be potted first into 6-inch pots, and when these are moderately filled with roots, say in six or eight weeks, the plants should have their final shift—viz., into 9-inch pots. The principal object in giving them their final shift while yet small plants being to induce them to make plenty of roots in advance of growth, which will consequently be free and vigorous. They may then be allowed to grow naturally, or may have all side shoots removed as they appear, and simply grown on single stems as columns. *Crotons* grown in this latter style are, in my opinion, more thoroughly effective and elegant, as well as generally useful, than when grown in any other shape, and most of the varieties may be grown in this style, although some are better adapted for it than others. Such sorts as *Warreni*, *Princess of Wales*, *Prince of Wales*, *Johannis*, *Sinitzianus*, *Anietumensis*, and *Rodeckianus* of the long narrow-leaf section, and *Evansianus*, *Baroness James de Rothschild*, *Morti*, *Bachi*, and *Variegatus elegans*, of the broad-leaf section, make superb plants grown on this system. I have had *Warreni* with leaves fully $2\frac{1}{2}$ feet long, and *Baroness de Rothschild* and *Evansianus* 6 feet high, without losing a leaf.

For table plants the pots should not exceed $5\frac{1}{2}$ inches in diameter, and the narrow-leaved section are the most suitable.

Crotons, like *Stephanotes*, *Gardenias*, and most other stove plants, are subject to that worst of all pests, mealy bug, as well as thrips and red spider; and in coping with these I advise working, as far as possible, on the principle of "prevention better than cure." Red spider may be kept down in a great measure by the free use of the syringe; but more harm to the plants is to be apprehended from these insidious little insects than from thrips or mealy bug, as they sometimes attack the young growth, checking the plant and causing the young leaves to fall off before we are aware of their presence. Hence the need for constant watchfulness. Red spider is easily destroyed by painting the hot-water pipes with sulphur and heating them very hot, but great care must be exercised when this remedy is resorted to, as, although it is not injurious to *Crotons*, yet it is fatal to many delicate plants, particularly some *Ferns*, *Adiantum farleyense* for instance.

On the least appearance of thrips the plants should be fumigated immediately, as these insects rapidly increase, and a stitch in time often saves nine. The fumigating should be done carefully two evenings in succession. Mealy bug is the worst pest to which *Crotons* are subject, and we all know of a dozen or more of so-called remedies, such as Gishurst compound, Abyssinian mixture, Fir tree

oil, &c., but I am not acquainted with any remedy which is in every respect satisfactory. Paraffin oil, of which we heard a good deal, is no doubt a fairly good remedy if mixed with water in the proportion of an ordinary wineglassful to three gallons of water. This must be thoroughly mixed and kept well stirred while it is being syringed on to the plants. It should be allowed to remain on the plants ten minutes, and then syringed off with clean water. I recommend this remedy for large plants only, and where they cannot well be dispensed with, small plants should be sponged with clean water.—H. RANGER, *Aigburth Nurseries, Liverpool*.—(Read at the December meeting of the Liverpool Horticultural Association.)

NOTES FROM A SCOTTISH GARDEN.

A Mild Winter.—From all parts of our "north country" we hear of the unusual mildness of the present winter, mavis singing and spring flowers blooming as if it were the month of March instead of New Year's day. In our garden it has been possible to cut a few *Roses* at any time, both *Teas* and *H.P.'s*. *Mignonette* is fresh and good, *Schizostylis coccinea* finer than it has been for several years, *Salvia fulgens* glowing, and *Vesuvius Pelargoniums* in vases covered with trusses—small, indeed, but wonderful for the 1st of January. The *Strawberry Trees* are now in full blossom, also the common tree *Ivy*, and the sweet *Laurustinus* has, after the lapse of several years, yielded a profusion of trusses which are now opening their flowers. In the borders and on the rockery *Iberises*, *Primroses*, &c., have met the late *Asters*, *Violas*, and *Pentstemons*. Everywhere the spring flowers are moving. *Sisyrinchiums* are several inches above the soil, *Crocuses*, *Daffodils* and *Snowdrops* are peeping above ground, *Doronicums* are showing their buds, and in the frames the *Auriculas* and *Polyanthuses* are starting. Among the fruit trees the *Black Currants* are showing their light-green whitish buds very prominently. *Raspberry* buds are also swelling.

Tillandsia Lindenii.—We have had a plant of the above in bloom for the past two months, and although in colour not so dark as those that are called the best varieties, its light blue and white flowers are very pretty. The plant in question produced a central spike which flowered first, and half a dozen side spikes which are now flowering. The plant is blooming in the 4-inch pot in which it was struck from a cutting.

Aphelandra aurantiaca.—This is another not commonly grown stove plant which flowers at this season. It is best propagated from seed which, sown as soon as ripe, and the young plants attended to, produce good strong flowering plants the following winter. They do well in 4-inch pots, and may be grown in turfy loam.

Eucharis amazonica.—Is there any necessity for resting *Eucharises*? With an abundant supply of heat at command we have kept the plants growing freely, and we are never without flowers; not, of course, a great number at one time, for that is not required for home use, but a sufficient number for our needs.

Pancratium speciosum.—With this lovely plant we are adopting the same mode of culture. It seems as if it could enjoy any amount of heat all the year round. With plenty of heat to keep root growth active, the present is a good time to repot this *Pancratium*, which does well in turfy loam with good drainage to the pot.

Carnations.—There are some flowers which a gardener can hardly produce in too great a quantity, and amongst these are *Carnations*. Miss Joliffe is the beau ideal as to habit and floriferousness of what a good winter-flowering *Carnation* ought to be; it is also a pleasing shade of light rose. An equally good white would be of great value. Will any of your correspondents be kind enough to name a white *Carnation* they have proved to be free-flowering throughout the winter months, and which produces cuttings freely for propagating at this time? We do not want the flowers large but plenty of them.

Late and Useful Chrysanthemums.—The *Chrysanthemum* season has been a very good one and the bloom prolonged. *Fair Maid of Guernsey* we have still in quantity, and late-struck plants of *Ethel* are not yet in flower. This variety requires a little heat now. *Fair Maid* has been the best white of the season, both the flowers from side growths and the terminal ones being good. Unlike *Elaine*, which turns pinkish with age, this variety retains its purity for a long time. *Lady Selborne*, about which I sent a note last year, has also the same good property. We cut the last

of this kind, good blooms, in the last week of December. I do not find any varieties so much liked as Mrs. G. Rundle, Mrs. Dixon, and Mr. G. Glenny. Madame Desgranges is an excellent early white. Julie Lagravère is yielding a good supply of blooms now.—X.

GROWING PEAS IN POTS.

A DISH of Green Peas is always most acceptable even in the season of their abundance outside, but more especially are they esteemed early in the year—that is, during April and May. A good dish sent to table at this season will always give pleasure and satisfaction. Although to produce them in any quantity thus early requires considerable space and rather more than ordinary care, some gatherings may be obtained by those having two or three Peach houses or vineries. The best way to grow them is in pots. The first batch should be sown at the beginning of October; use 8-inch pots and provide ample drainage. The soil should consist of three parts loam and one part manure, with the addition of some burnt refuse. The quantity of this will depend upon the nature of the loam. If heavy use it liberally; if light not much will be required. Press the soil into the pots rather firmly, about three parts filling them, then sow twelve peas in each pot, distributing them evenly over the surface; cover them with soil, which should not be pressed down until after the peas are up, when with the addition of a little more soil the surface should be made firm. We find the plants are less liable to damp off when the surface is firm.

When the seeds are sown place the pots in a cool airy position, a shelf along the front of the early Peach house will suit them well; here the Peas will germinate and grow 2 or 3 inches before the time comes for starting the house. In this position they may remain, and be allowed to come on with the Peaches, and if carefully attended to a gathering may be had from them about the end of April or beginning of May. Another batch should be sown at the beginning of December and placed in a light position in a Peach house or vinery that is just being started. Several successional batches should be sown at intervals of a few weeks, according to the space at command.

We sow fifty pots at a time, and generally obtain several good gatherings from each batch. Great care should be exercised in the watering. It is better to err on the side of giving too little than too much, as if the soil becomes very wet damping-off and mildew is sure to be the result. On the other hand, if kept too dry the blossoms will turn yellow and fall off before expanding, but if the pots have been properly drained either of these evils will be easily guarded against. The young plants should be supported by some twiggy sticks before they begin to fall about, or four sticks may be inserted round the sides of the pots, and some pieces of matting strained round them. As the plants grow allow room enough for the air to circulate freely amongst them at all times. More especially is this desirable when they are in flower, as it will materially assist the setting. As soon as the pods commence swelling assist them with a little guano water or Clay's fertiliser, but do not use either strong. Many tender forced plants are spoiled by the use of stimulants, because they are used too strong. A handful of guano to a four-gallon can of water is sufficient, and a teaspoonful of Clay's fertiliser to an 8-inch pot sprinkled over the surface of the soil twice a week will soon have a beneficial effect.

Mildew is often very troublesome, and should be attended to immediately it makes its appearance by dusting the affected parts with flowers of sulphur. This can be done without smothering the plants with it, as is sometimes seen, giving them an unsightly appearance. If carefully applied to the upper and under sides of the foliage where the mildew has shown it will soon have the desired effect.

Varieties.—We used to grow McLean's Little Gem, but American Wonder sent out by Messrs. Sutton & Sons will quite supersede it, as it is much dwarfer and earlier, it is also a good setter, the pods invariably being well filled, and the quality excellent.—A. BARKER, *Hindlip Gardens*.

SCOLIOPUS BIGELOVIL.

THE plant shown in fig. 4 is a member of a very remarkable new genus. It was found by Dr. Bigelow at Tamul Pass, Marin County, not far from San Francisco, and is, I believe, confined to that locality. It was first put at the end of Melanthaceæ, but in Hooker's "Genera Plantarum" has been placed between Clintonia and Medeola in Liliaceæ. Although it is now some years since it was first introduced it is as yet very rare in this country.

It flowers early in April and May, the number of blooms being invariably eight in different stages of development. The flowers are beautifully crisped, not unlike *Nerium crispa*, and vary from a dull greenish to a bright showy purple, regularly interspersed with dark

spots, often merging into blotches. The outer segments are about an inch long, nearly half as broad, and widely spreading. The inner ones are about the same length, very narrow and erect, but variable. The leaves are from 6 to 8 inches long and half as broad. They are very suggestive of *Veratrum*s, and only differ from them in having the veins on the under surface narrowly winged, both sides being sprinkled with minute purple dots, making them very attractive.

The plant is perfectly hardy in our climate, and only requires to be

Fig. 4.—*Scoliopus Bigelovii*.

known to be generally cultivated. It should be planted in a peaty soil in a partial shady position, with much the same treatment as that given to *Trilliums*. A coloured plate appeared in the "Gartenflora" for 1875, which, however, was from a plant in a pot, and does not do it anything like justice. It is well grown by Mr. T. S. Ware of Tottenham, and the above figure was drawn from a plant that flowered in his nursery last year.—M. S.

SPECIAL SOCIETIES.

MY only object in writing the note (page 549, last vol.) to which Mr. Douglas took exception last week was to express, what is the opinion of myself amongst numbers of other growers, that the results effected by these special societies are by no means equal to the expenditure incurred. A few who have made a speciality of such plants would have continued to grow them with equal ardour had no such societies been called into existence, and these reap nearly all the advantages—that is, they are almost assured of gaining a certain number of prizes every time they exhibit, because they know the exact strength of what few competitors appear. The only conclusion that can be drawn is what I have previously stated—namely, that the prizetaking is practically a monopoly. I have frequently seen and admired the flowers exhibited by Mr. Douglas at the Auricula and Carnation shows, and no one, I am sure, would begrudge him the honours he has won, and several other deservedly noted growers could be named with him. But that is not enough. A society with the title of National should be of national utility, and I fear that such is not the case with either of the three societies named. Perhaps, however, Mr. Douglas can bring forward conclusive evidence that the Pelargonium, Auricula, and Carnation Societies have during the period of their existence really increased the number of growers and admirers of those plants to

an extent at all commensurate with the outlay. If he can I shall be glad to see that their efforts have been more successful than I at present believe to be the case.

With regard to the schedules which the Editor has kindly forwarded to me from Mr. Douglas, I wish to ask, What is the reason why, in the classes for single specimen Auriculas, one grower is allowed to take all the prizes offered? Indeed, as I understand it, it is quite possible for one exhibitor to take all the prizes in all the sections of this class. Does your correspondent think this is exactly right?—X.

MOSS AND LICHENS ON APPLE TREES.

THE chief cause of this is simply a damp situation, the fruit trees being surrounded by taller trees which never allow the branches to become dry for months together. I have just examined a large number of trees covered by the above which were blown down by the late gale. They have fine, clean, healthy-looking roots close to the top of the soil, which is deep and on limestone; the roots and soil on closer examination appear to be mouldy and sour.

The branches of every tree must be thinned and shortened, the roots well manured, and just before the blossom opens syringe with soft soap and petroleum. This destroys the blight and vermin as well as moss, and will insure more and finer fruit. High trees are very baneful to orchards, often destroying what they were planted to protect.

I have pruned no fruit trees since cutting the breastwood to admit the sun to ripen the fruit, and I do not intend to prune my standards at all this season, as all have had the centres cut out and been root-pruned recently. Fruit trees will suffer very much this winter from the mild wet weather, unripe wood, soft buds, and early show of bloom. I have never noticed any harm from late or spring pruning. Early pruning and a mild winter like this spread disease.

The reason I advise syringing before the blossom opens is to reduce the danger of using the mixture too strong or badly mixed. The unopened trusses are also often covered with vermin, and those are destroyed before they get into the blossoms. The trees should be syringed with clear water before using the mixture.

Gas tar well mixed with water and used like the above is very destructive to the fly on the Pear leaf.—J. E. WAITING, *Grange-over-Sands*

AT a General Meeting of the ROYAL HORTICULTURAL SOCIETY, held last Tuesday, Henry Little, Esq., in the chair, the following candidates were unanimously elected Fellows, viz.:—Thomas P. Bethell, Viscount Enfield, Sebastian Waterhouse, Rev. Christopher S. Watson.

— WE have received from Messrs. Rivers & Son of Sawbridgeworth fruit of the BIJOU LEMON, a charming little fruit of the size and shape of the Lady Apple. It is quite oblate, with a depressed crown, in the centre of which is a small swelling bearing the style point. The skin is remarkably thin, and the flesh very juicy with a fine brisk Lemon flavour.

— THE eminent naturalist and physiologist, PROFESSOR RICHARD OWEN, has been honoured with knighthood. For many years he has been the chief in charge of the natural history collection at the British Museum, and was one of the principal projectors of the Natural History Museum at South Kensington, but has recently resigned the above charge. This recognition of the services he has rendered is well merited.

— SOME of our readers will learn with regret that the directorate of the PELARGONIUM SOCIETY have brought their labours to a conclusion, as, owing to the inadequate support afforded, arrangements could not be made for another show. They have terminated their work with a money balance in their favour, and some members propose that this be given to the National Auricula and Carnation Societies.

— THE remarkable ABSENCE OF SUN that has been experienced of late has been the reverse of favourable to early forcing operations. In the meteorological report issued last Monday from the Greenwich Observatory, it is stated that the sun re-appeared on Sunday the 6th inst. for the first time since the 23rd ult. The maximum temperature in the metropolis on the same day was 51°.

— AN admirable plant for the winter decoration of the greenhouse, and one rarely met with except in large establishments, is the beautiful *SENECIO GHEISBREGHTII*. It grows from 8 to 10 feet in height, with leaves about a foot long and half as broad, of a thick leathery character.

The flowers, which are borne in large corymbose heads, are golden yellow and very attractive. Small plants in 4-inch pots are useful as decorative foliage plants, thriving well under ordinary greenhouse treatment.

— THE fixtures of the ROYAL HORTICULTURAL SOCIETY OF IRELAND for 1884 are as follow:—Spring Exhibition, Thursday, April 17th; May do., Thursday, May 15th; Summer do., Thursday, July 3rd; Autumn do., Thursday, August 28th; Winter do., Thursday, November 20th.

— PEACHES AT CHRISTMAS.—We are informed that Mr. Lamb, gardener to Sir Henry Pottinger, Bart., The Hermitage, Chester-le-Street, Durham, sent in a dish of Peaches on Christmas day from a tree three years old in a 9-inch pot. It is a new variety named Osprey. The Peaches were medium-sized, rich in colour, and were much admired at the dinner table.

— TWO of the most abundant flowers in Covent Garden last week were *CALANTHE VEITCHII* and *CENTROPOGON LUCYANUS*, of which large bunches were to be seen in several of the principal florists' shops. The first-named was especially fine, the spikes 18 inches or 2 feet long, closely set with large flowers, but mostly rather pale in colour. They were evidently the produce of extremely vigorous plants, and they must be grown in quantity to furnish so large a supply. The old *Centropogon* was similarly strong, but in this case the flowers were remarkably highly coloured, the peculiar deep rose tint being very freely developed.

— OWING to the very mild season HARDY FLOWERS are more plentiful just now than they have been for some years, and lovers of these will have no difficulty in supplying enough for table decoration. The following are flowering in the neighbourhood of London:—*Anemone reginae*, *A. vitifolia*; *Arabises Stelleri*, *albida*, *alpina*, *procurrens*; *Aubrietia olympica*; *Armerias plantaginea* and *longiaristata*; *Coronilla securigera*; *Crocuses laevigatus*, *Imperatri*, *alatavicus*, and *longiflorus*, *Chrysanthemum leucanthemum*, *Cyclamen*, *Cheiranthus Cheiri*, *Galanthus nivalis* (Snowdrop), *Geum pyrenaicum*, *Helianthemum rosmarinifolium*, *Helleborus niger*, *H. foetidus*, *Houstonia cœrulea*, *Ionopsidium acaule*, *Kniphofia sarmentosa*, *Narcissus Tazetta* var. *aureus*, *Omphalodes verna*, *O. verna alba*, *Primula denticulata*, *Polygala Chamæbuxus roseus*, *Potentilla alba*, *Trollius europæa* var., *Viola lutea grandiflora*, *V. odorata*, *V. tricolor maxima*, and *V. hederacea*, *Vaccinium Vitis-Idæa*, *Veronica spicata*. Shrubs—*Chimonanthus fragrans grandiflora*, *Jasminum nudiflorum*, *Discaria longispina*, and *Rosa indica*.

— THE schedule of the INTERNATIONAL HEALTH EXHIBITION to be held at South Kensington this year has been issued, and contains full particulars of the regulations and classes, together with a list of the members of the Council and officers. The exhibits will be classified in two great divisions—viz., health and education. The first including groups for food, oven, the dwelling house, the school, and the workshop, each also containing a number of classes, forty-six in all. Under Education are arranged ten classes to be illustrative of educational works and appliances. The Exhibition will be opened on May 1st, and continue open for not less than six months.

— "THE most FAMOUS TREE IN PARIS is," states a correspondent, "about to disappear—viz., the *Février* or *Gleditschia* of the National Library. It was planted about a century ago on the spot now occupied by the reading-room, and Robinson Crusoe being then in full vogue a legend sprang up that this was the tree on which Selkirk passed his first night on his island. It is believed to have been planted as a tree of liberty in 1789, and was the gift of the English botanist Catesby. In 1859 on the erection of the reading-room it had to be removed 50 yards to the court of the library—a difficult task, for it was 60 feet high, and the expense amounted to 8000 francs. The court after the enlargement of the library is about to be paved, and the tree is to be felled."

— A CORRESPONDENT writes that "Mr. M. D. Thompson, gardener to Lindsay Wood, Esq., South Hill, Shields, makes a special feature of having a good display of FLOWERS AT CHRISTMAS. In his large conservatory (one part exotic the other greenhouse) was a grand display of *Calanthes vestita lutea* and the charming *C. Veitchii*. Of the latter some of the spikes had as many as thirty-five to thirty-six flowers each; these plants were placed at the margin of the central arrangement of the house, and the pendant spikes had a graceful effect, springing from a margin of Ferns and Lycopods. The cooler division of this house is now

occupied with Camellias flowering freely, Richardias, Azalea amœna, Roman Hyacinths, Tulips, and fine Cyclamens. Lily of the Valley was also plentiful, this Mr. Thompson is very successful in forcing. In the stoves we observed Phajus grandiflora growing strongly, while the charming Oncidium obrysatum was showing fourteen spikes. In one of the vineries against the wall is planted Tropæolum Ball of Fire; this has been allowed since the Vines have gone to rest to run down the canes, the consequence is just now that the growths are full of bloom and are as good as Pelargoniums to cut from.

THE GOOD YOUNG MEN OF OLD.

YOUR correspondent "H., Notts," in his retrospect of the last thirty years, pays a very poor compliment to the young gardeners of the period; and as one of them I trust you will allow space for my few remarks in our defence. It occurs to me that "H., Notts," is one of these persons who cling with tenacity to the days of their prime, and who are prejudiced against everything and everybody of the present day. This is evident from his laudatory reference to the writers of old in preference to our modern scribes, whose articles in the pages of the Journal I venture to assert will compare more than favourably with anything that appeared in any gardening periodical of thirty years ago, whether scientific or practical.

Gardening has most assuredly made rapid strides since "H." and his colleagues so assiduously studied the current literature, "not skimmingly, as the young men of the present;" but progress in future must indeed be slow if all "H.'s" assertions be true, which I deny. True, there are many who serve a few years at gardening, but not proving worthy of the calling have to relinquish it; yet the majority of young gardeners are, I hold, a credit both to themselves and their calling, and will in turn prove as good trainers to the future generation as many of the existing staff of head gardeners are of the young men of the present. Perhaps I am wrong; but I maintain that head gardeners are not altogether faultless, and not all of them treat their subordinates as members of their own craft. What a different state of things exists where the head gardener takes his men partly into his confidence and converses freely on horticultural topics, thereby introducing harmony into all the daily duties, and gaining for himself the respect of his young men, in itself an unspeakable satisfaction.

"H., Notts," also refers in tones of high praise to "A Working Gardener's" letter to young men. Granted the advice there given to be good, it carries but little weight unless based on practice. Let "Working Gardener" first practise, then preach. Singing classes are not approved of, but I would say to every young man having an ear for music, Cultivate that taste; it is a harmless pastime and an intellectual recreation. The man who spends one evening in the week at a singing class can, I have no doubt, perform as much dry study in the remaining evenings as another would in a full week. Had "H., Notts," been a musician he would not have written in his melancholy style. I shall conclude with urging my young fellow men to keep on plodding, and read all essays and attend all public lectures they can that tend to their self-improvement.—T. L.

[Our correspondent has no right to insinuate that a "Working Gardener" does not practise what he preaches. He is one of the most skilled and accomplished of gardeners, and his many communications, founded on practice, rank amongst the most useful that have ever appeared in our columns.]

I CANNOT agree with your correspondent "H., Notts," in what he says about the young gardeners of the present day in your issue of the 27th. I fail to see why they should be so much worse than their predecessors. Perhaps when "H., Notts," was a young man the head gardeners were not quite so high in the world as they are now. I hope some of the young gardeners will learn something from your correspondent, but I think he might be a little more lenient, and instead of being harsh give us a hint how he managed to do so well and not go astray. He would then be doing service to gardeners young and old; some of the seed would be sure to fall on good ground, and we should ever bless him. I would like to thank him, also "A Working Gardener," for kindly calling our attention to the state we are drifting into, and I hope before this year is out he will be able to say we are improved.—T. R. M.

STORED-UP SAP IN VINES.

IN justice to myself and those who have supported me in this matter, allow me to place these two passages in juxtaposition in order to show your readers how Mr. Taylor stands now. At page 396 in my first note I said, "It is impossible to reconcile Mr. Taylor's theory of stored-up sap in Vines (p. 372) with facts or common observation, and I believe there are few experienced gardeners who believe that Vines subsist on 'the stored-up food' of the previous autumn till the shoots are 7 inches long and the leaves 5 inches broad, as Mr. Taylor states." In his last note Mr. Taylor says, "Now for the little bit of theory which has caused so much discussion. It is to the effect that the appearances noted above and recorded within inverted commas 'indicate that the roots have commenced action, and that the leaves are no longer dependent on the stored-up food which was prepared last autumn and preserved in the stems for

early use,' True this is pure theory, in which, as far as I know, I am not supported to the full length by any professed physiologist."

For "professed physiologists" substitute "experienced gardeners," which means much the same thing, and Mr. Taylor and I are quite agreed about himself. His words here look very like a confession of error, and an acknowledgement of the correctness of my first words. I beg, however, to tell Mr. Taylor in the most unequivocal manner that he did not advance the above statement of his in inverted commas as a "little bit of theory," but as a *fact* in practice; and instead of saying or admitting that "professed physiologists" did "not support him," he quoted them to prove that they did, and attempted to twit his opponent with ignorance of the latest authorities on the subject. This is Mr. Taylor's true position in this discussion. I regard his last statements as neither more nor less than an ungracious submission to the force of the evidence from several sources which has been brought against him. His latest idea that "the Vine has an economy peculiar to itself" is just as groundless as his other assertions.—NON-BELIEVER.

WILTON HOUSE.

CONTINUING the record of these excellent gardens from page 11, we arrived at a range of pits, in one division of which the most celebrated of the occupants are undoubtedly the Vines "growing without soil." Some persons fail to grow Grapes with whatever soil they are supplied with, others succeed as it were independently of soil. Some of the best Black Hamburgs I ever saw and tasted were grown in a bed of leaves and manure, no loam being used, by Mr. Hunter at Lambton Castle; and now at Wilton I find Vines of the same variety in admirable condition, and produce Grapes of the highest quality without either manure or loam in the border. At the time of planting, a "soil difficulty" having arisen, Mr. Challis resolved to try an experiment. Rather than plant in what he knew was unsuitable soil that was supplied him, he determined to plant a pit without any soil at all. If I remember rightly the compost is as follows:—One-fourth of broken bones, one-fourth of lime rubbish, one-fourth of bruised charcoal, and one-fourth of pounded bricks. If this is not the mixture I shall be favoured by being corrected. In such out-of-the-way material the Vines were planted and the surface mulched with manure. With good attention they made steady solid progress, and have for years afforded fruit superior in quality to all others in the garden. In the same house, on the opposite side of the path, Vines are planted in a border of good Vine-growing soil, and the rods are trained down alternately with the others, but the rods are the finest and hardest, and the Grapes invariably the best that are grown in the soilless border. There is no mistake about this. It is a simple record of facts, and the truth cannot be told in any other way. There is not a particle of sensationalism about it any more than there is in the character of the quiet studious gardener, the author of the experiment; and he, as all who know him will readily admit, is among the last persons in the world who have the slightest disposition to draw the long-bow. But let it be remembered that success of the kind indicated can only be achieved by masters in the art of Grape culture, and amateurs and lovers of change generally would not act wisely by rushing headlong into a similar method of culture. If they have good results in the good old way let them be content to travel in it; it is only on a small scale, and experimentally, that these innovations can be wisely indulged, however well the above-named practice has answered at Wilton.

Another range of similar dimensions is occupied with plants, of which there is an enormous demand for decorative purposes and affording flowers for cutting. It must suffice to say that all the popular kinds are largely and excellently grown, and that there is a remarkably fine collection of Orchids, not a few species being represented by such grand old specimens as are not seen every day; and that a houseful of seedling Cactuses, or rather Phyllocactuses, was not a common sight. Having been raised from fertilised flowers and the plants approaching the flowering stage, they are being watched with some interest. I only know one other similar batch of seedlings in a private garden—namely, Mr. Major's, at Cromwell House, Croydon. If these hybridisers and lovers of old plants should make Cactuses once more fashionable patience will have had its merited reward; and since the Sunflower mania nothing is impossible in the floral world.

We pass on, and pass through quickly, the last range in this block. It is larger than the others, has been twice filled with splendid Vines, and once emptied in consequence of the presence of the great Vine scourge the phylloxera. The victim of a double outbreak Mr. Challis is to be pitied, and the only thing consolatory about the matter is that by his close observations and investigations he may be able to obtain knowledge of the life history of the insect, and methods of subduing it that may be useful to others. We will leave this unfortunate house and pass to another range of no common excellence.

A GRAND PEACH HOUSE.

The range, which includes divisions for Peaches and late Grapes, must rank amongst the most complete and best in the kingdom. It is 200 feet long; back wall 12 feet high, front of the house 7 feet, height to the ridge about 15 feet, angle of roof 37°. The back wall contains an air passage with perforated ventilators at the top on the outside, and at the bottom in the inside of the house. Provision is also made for a supply of heated air in front, apart from the ordinary method of ventilation, which is abundantly provided for both by the front lights and on both sides of the ridge, the whole worked by continuous crank movement with the greatest ease. Rafters 9 by 2 inches are placed

5 feet apart, and crossing them at right angles are $2\frac{1}{2}$ by $1\frac{1}{2}$ inch purlins, to which the glass is attached. The glass covers the entire woodwork, the squares being fixed by a method which, after studying most others, Mr. Challis devised for himself. It is extremely simple and absolutely strong, the roof drip-proof but not air-proof. A square can be removed in a moment from any portion of the roof and replaced. This is done from the inside, so there is no difficulty in the matter of repairs, if such should be needed. The glass is fixed in copper clips that are secured to the purlins by nails of the same metal; two clips to each pane of 24 inches by 18 inches, the laps of the glass being immediately over the purlins. The clips are punched, slight elevated points being thus formed on the opposite side. On these the glass rests, hence a free passage is afforded for any condensed moisture to trickle through and on to the square below, while at the same time it follows that the space for the exit of moisture is available for the ingress of air. In a roof thus glazed there is small chance of the foliage of trees or Vines scorching, and the probability is similarly remote of the space between the laps being filled with water or ice, which in the one case seals the roof, and

now, the difficulty being to secure the edge of the trellis firmly next the path, as obviously the second row could not be in line with the supporting column under each rafter. Given a light roof this is unquestionably the best method of arrangement and planting a tolerably large Peach house, as not only can the back wall be covered with fruitful trees, but the trellis surface is much greater than by the common form of arching over the border or training the trees under the roof after the manner of Vines. By the single cross trellises, and the occupation of space overhead, Mr. Challis has ascertained that he obtains three and a half times the bearing surface over that afforded by an ordinary curvilinear trellis formed over the border; and with a double row of trees the surface would be proportionally increased. The gain would, of course, not be so great in low and narrow houses; but the economical plan to adopt by those who desire the greatest amount of produce for their outlay is to erect wide and lofty structures as light as possible. But what of the trees in the house under notice? They had been planted three years, and every inch of the trellises was covered. Only twice before have I seen such rapid growth—once at Wortley, young trees grown by Mr. Simpson under

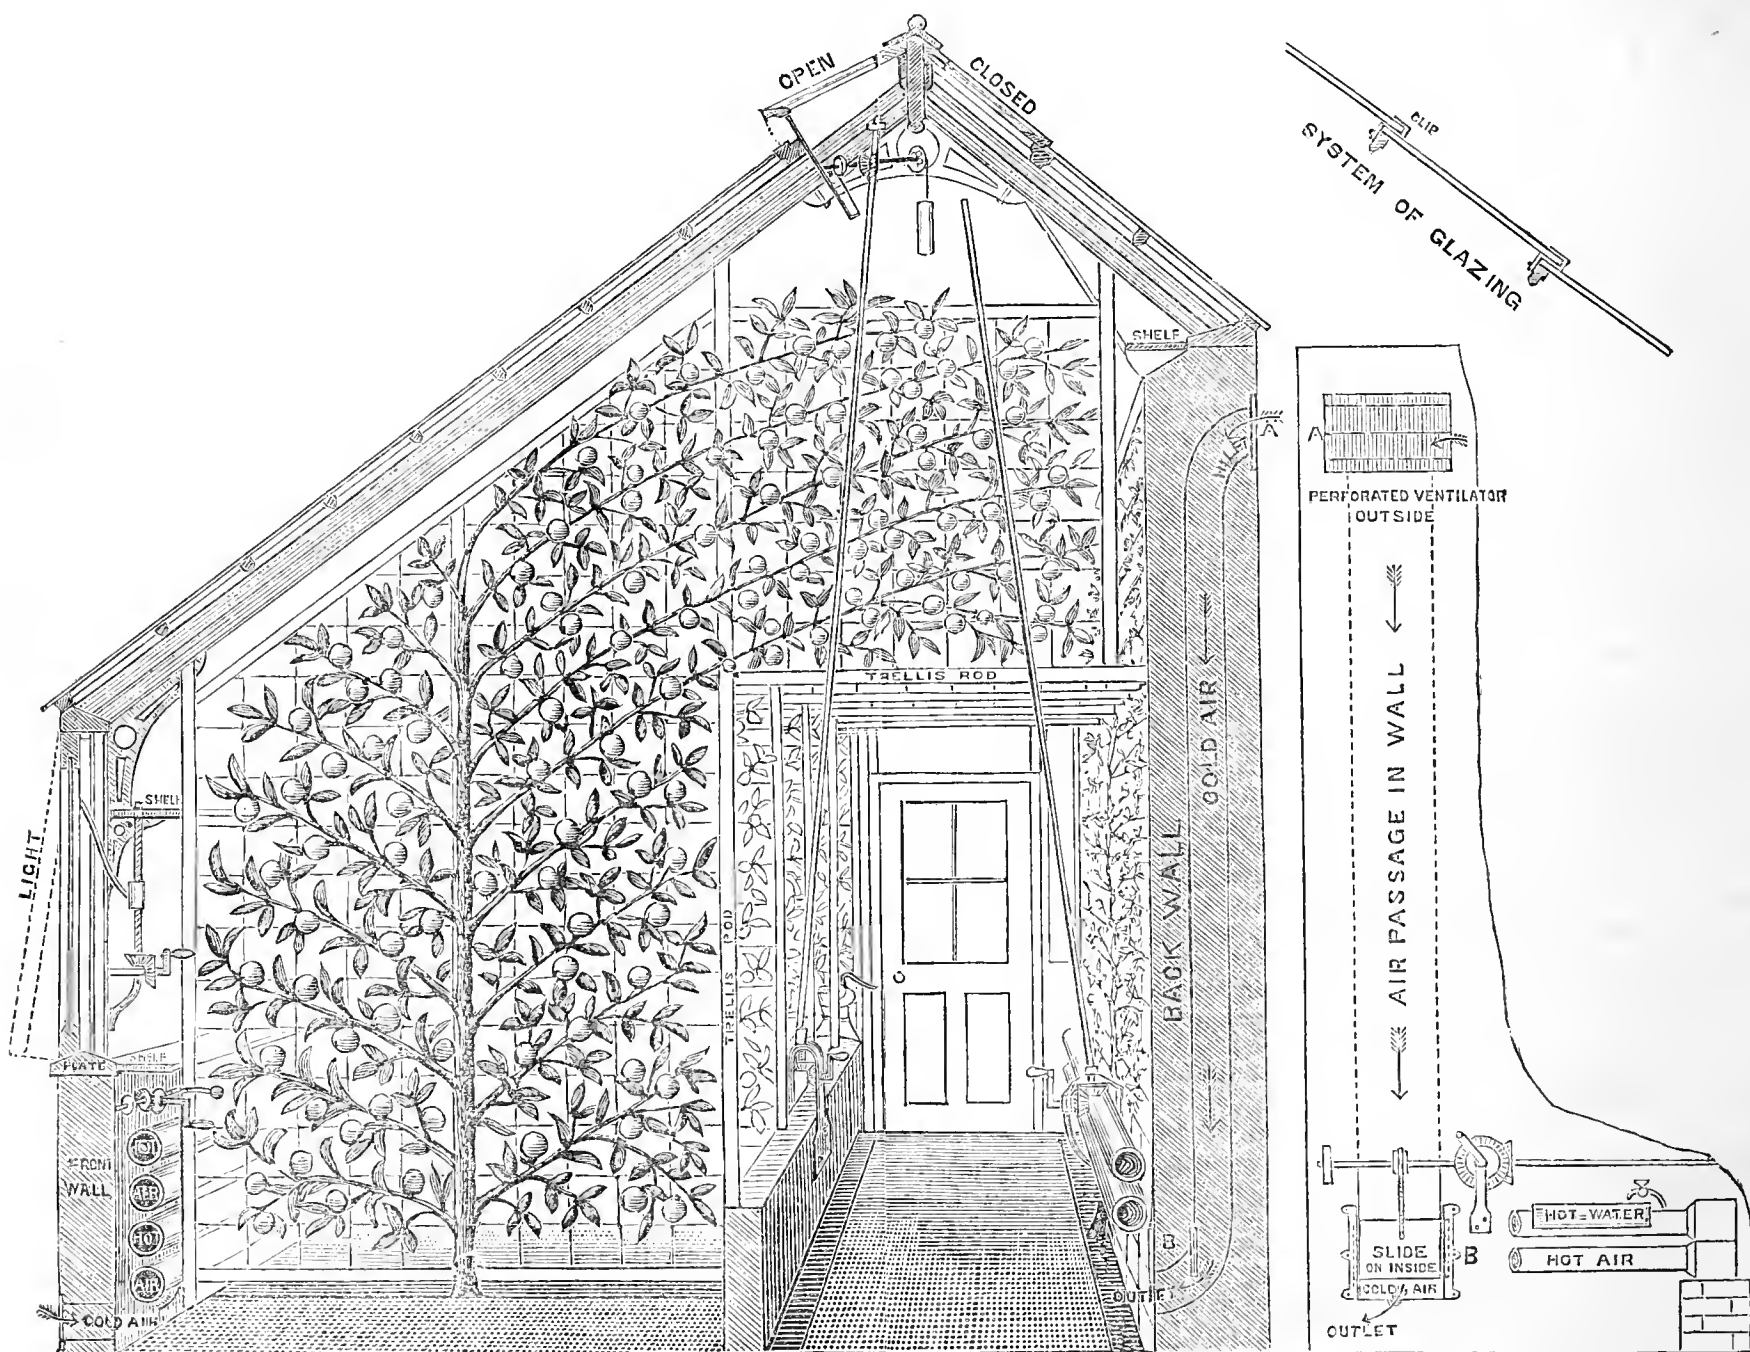

Fig. 5.—PEACH HOUSE AT WILTON.

in the other is liable to cause breakage of the glass. The strength of this system of glazing was accidentally tested. A span-roofed Rose house was being covered. One side was done when a violent storm rose. Although the wind, which uprooted trees, blew directly on the under side of the glazed portion for hours, not a square was transfixed, and the safety of the method was established.

The Peach house is trellised across the border from the ground to the roof, also over the doors and path to the back wall, which also is wired and covered with trees. The vertical trellises are 5 feet apart—that is, one under each rafter, and the light iron columns that support the roof act also as supports to the trellises next the walk. In one instance a double row of trees is formed across the border, the space between the trees being about a foot, and experience has shown that practically twice the quantity of fruit is obtained by this arrangement, or, in other words, the addition of a second row has not impaired the producing power of the first. This is a distinct gain, and it is certain that if Mr. Challis were erecting another Peach house similarly large and light, provision would be made for having double rows of trees across the border; indeed it is not improbable that some scheme will be devised for having them

glass; and previously at Oldlands, with trees on an open wall grown by Mr. Luckhurst, and in all three instances the fruit produced by this generous system of culture was of the first size, colour, and quality. The back walls of the houses are covered with Figs which, receiving abundance of light, thrive satisfactorily.

The varieties of Peaches and a few Nectarines which are found to give a long succession of superior fruit at Wilton are the following, which ripen somewhat in the order named. Early house—Early Beatrice, Early Louise, Hales' Early, Dr. Hogg, Grosse Mignonne, Stirling Castle, with Rivers' Early Orange and Elruge Nectarines. Second house—Royal George, Noblesse, Exquisite, Barrington, Walburton Admirable, with Violette Hâtive, Pine Apple, and Victoria Nectarines.

As affording a better idea than can be conveyed in writing of the trellis arrangement in the houses in question, a figure is introduced of the end division. The top ventilating gear on the north side, which is not shown, being similar to that on the south side. The hot-air pipes and perforated ventilators are shown at back and front, and the arrangements will now be comprehended. The walls are of cement. The method of glazing is given except the indentations in the clips for

forming the points on which the glass rests, instead of one pane resting on the other. This is a simple but important feature for the reasons above stated.

Like Lord Herbert, previously referred to, the present Earl and Countess of Pembroke appear to be great improvers, as it was by their decision that this splendid range was built, and it was through the combined thoughts and efforts of the agent on the estate, as well as the clerk of the works and gardener, that their instructions were carried out. The whole of the work was executed by workmen on the estate, with the exception of the heating, which was satisfactorily performed by Messrs. Weeks & Co., simply by an addition of pipes to the apparatus arranged formerly by them.

In line with the Peach houses are three noble vineries admirably furnished with late Grapes—Muscats, Lady Downe's, and Mrs. Pince, with Alicantes and Gros Colmans on the back wall. The Vines on the roof are as fine as can be desired, and those on the back wall as good as could be expected. For such a position the Black Alicante is the best variety. This is apparent at Wilton, as it was in Mr. Witherspoon's great vinery at Chester-le-Street, which I had the pleasure of inspecting a few years ago, and it will be long before the spectacle vanishes from my memory. This hint about Black Alicante is given in case there may be persons desirous of trying Vines against the back walls of their houses as well as overhead. The variety named appears to endure shade better than any other, but I say nothing about the quality of the fruit. The houses vary in width from 15 to 19 feet according to the configuration of the ground.

The structures at Wilton are well and satisfactorily heated by two miles and a half of hot-water pipes from one of Weeks' tubular boilers. Mushroom houses, fruit rooms, and all necessary appurtenances are represented in the most approved manner; indeed, only a little appears to be wanted to render the garden complete, and that little, additional space for growing plants. In this department overcrowding perforce prevails in maintaining the great supply of plants and flowers for the adornment of the mansion. In the summer flowers are afforded by an extensive collection of herbaceous plants, but during six months of the year they must be produced under glass.

This is all I can remember about historic Wilton, the ancestral home of a noble family—noble in deed as well as birth, as is shown by their kindness and consideration to all tenants and employés. No, not quite all, for there is the not-to-be-forgotten kindness of Mr. and Mrs. Challis extended to me during my short sojourn at this grand old place, the head centre of the ancient capital of the county in which it stands.—J. WRIGHT.

BOTHY LIFE—ROOMS AT KEW.

"LIBERTAS" has approached this subject in a very considerate manner, and this gives me hope that he will as readily acknowledge the weak points of his arguments when placed before him. His two principal objections to the scheme are, first, that the conditions in a public establishment like that at Kew and those in ordinary private gardens are very different; and second, that were such a bothy erected it would be difficult or impossible to maintain order. Regarding his first objection, the difference is not so great as he would have us believe; for though the gardeners at Kew have not to attend to the fires, they have to attend lectures and the reading-room, which equally require their presence in the gardens during the evening, so that "Libertas's" argument on this point is practically without support.

The second objection—namely, that it would be difficult to maintain order amongst so many young men, also seems at first glance very feasible, but it will not bear close examination. For instance, "Libertas" states that in private gardens in a bothy containing six young men there are usually two foremen who preserve the necessary order, but I may add that more frequently there is not more than one foreman to that number of men. Now at Kew there are between thirty and forty young gardeners, and there are three foremen in charge of departments; but there are also four advanced gardeners who in position more nearly resemble foremen in private gardens. We thus have seven officials who presumably owe their advancement to their abilities as cultivators, their steadiness and good moral characters, and who therefore may be expected to command the respect of the men generally. There would be a reliable official to every five young men, and is "Libertas" prepared to assert that the foremen at Kew are less capable of exercising the very moderate control that would be needed than are those in private gardens?

"Libertas" writes freely of "stringent rules," "proper supervision," and "strict discipline," as if he thinks it absolutely necessary that the men should be drilled like a regiment of soldiers, and that is the only portion of his letter in which I detect any appearance of unfairness. None of these restraints have been suggested except by him, and the proposal is calculated to check the free discussion of the subject by inspiring those concerned with a prejudice against the whole scheme. Has his opinion of the morals of the present young gardeners been formed on the same basis as that of "H. Notts?" I have known personally and intimately something like two hundred young gardeners, and my firm conviction is that for every one irreclaimably bad there are at least ten well conducted and disposed to do all they reasonably can to advance themselves in their profession. This is a good working majority, and is quite sufficient to keep the few in order, constituting, in fact, a species of self-government.

Further, judging by at least two sentences in your correspondent's

letter, I should say his "knowledge of the establishment" is very far from being "sufficient." He states first that "suitable lodgings are always within easy reach of the place," and as applied to Kew this is so obviously incorrect in every respect that it does not demand consideration after what has been stated by other correspondents. In another place he asserts that the time young men are supposed to stay at Kew "is not more than a year." There is no supposition of the kind. Young gardeners who go there know that they are not permanently engaged, and it would not be to their interest to remain for too long a period; but there is no rule expressed or implied to prevent a well-conducted young man from remaining two or three years if he wish to do so.—VERITAS.

JOSEPHINE DE MALINES PEAR—NORFOLK STONE PIPPIN APPLE.

HAVE any of your readers found their Josephine de Malines Pears ripen early this season? Our main crop was gathered on October 23rd, some a week later, some a few days earlier. They were ripe at Christmas, and are now nearly over. They grew well, perfectly clear, of a good size and of excellent flavour. They also coloured nicely on the tree, and kept sound until ripe; only one bad one in twenty-five dozen, a most unusual experience here with Pears. Should any of your readers living in exposed situations be thinking of planting Apple trees I would suggest that a trial be given to the White Pippin (or Norfolk Stone Pippin). Although small it is valuable on account of being able to withstand heavy gales without bruising. It is an excellent keeper, of first-class quality for cooking, and indeed is not to be despised for dessert in April and May.—C. B., *Swaffham*.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 8TH.

THE first meeting of the year was well attended by the members of the Committees, and exhibits were also numerous, one side of the conservatory being occupied with groups of Cyclamens, Orchids, Primulas, and miscellaneous plants. The exhibits before the Fruit Committee were confined to specimens of seedling and other Apples.

FRUIT COMMITTEE.—H. J. Veitch, Esq., in the chair. Mr. A. E. Townsend, Handsworth, Sheffield, sent a seedling Apple, said to have been raised from a cross with Striped Beefing and Winter Strawberry. It had close resemblance to Hoary Morning, but it did not possess any merit to recommend it. Messrs. T. Perkins & Sons, Northampton, sent a seedling Apple, No. 1, of handsome appearance and in good keeping condition. It is called Perkins' A1. It has a brilliant red cheek and a brisk acidity. It was considered a useful Apple, and was referred to Mr. Barron to prove its cooking qualities, to be reported to next meeting. No. 2 was considered of no merit. No. 3 was also of no merit, being past its season. Mr. Horley of Foddington, Beds, sent three seedling Apples, but neither of them possessed any merit. Mr. G. Brooks, Willington Park, Ilminster, sent a seedling Apple which had been exhibited at the Apple Congress by Mr. John Scott of Merriott, under the name of "John Scott's Favourite." It was considered the same as Round Winter Nonesuch. Rev. A. Carter, Tewin Parsonage, Hertford, sent three seedling Apples which did not possess any merit. Mr. R. H. Poynter, nurseryman, Taunton, sent specimens of Bess Pool. A collection of twelve varieties of Apples and two of Pears were exhibited by Captain Fernie of Chase Lodge, Mill Hill, N.W.

FLORAL COMMITTEE—Section A, General Plants.—Present, G. F. Wilson, Esq., in the chair, and Messrs. H. Ebbage, J. O'Brien, J. Dominy, H. Williams, J. Hudson, W. Herbst, John Woodbridge, John Fraser, John Laing, G. Henslow, E. Hill, and H. Ballantine. Section B, Florists' Flowers.—Present, Mr. Shirley Hibberd in the chair, and Messrs. H. Bennett, W. Bealby, J. James, J. Douglas, J. Child, G. Duffield, D. Lathbury, H. Cannell, and W. B. Kellock. A silver Banksian medal was awarded to Henry Little, Esq., Hillingdon Place, Uxbridge, for a beautiful group of Cyclamens, vigorous plants and profusely flowered; the very dark red form, Mrs. H. Little, was especially notable. Some good Primulas were also shown, and an interesting collection of Orchids, comprising Masdevallia tovarensis well flowered, Lycaste Skinneri atro-rubra, and virginalis, the former a very deep-coloured variety; Cypripedium Spicerianum, C. villosum Boxalli, Odontoglossum Roezlii superbum, one of the finest varieties in cultivation, and some fine varieties of Odontoglossum Alexandræ, together with flowers of Chimonanthus fragrans, and a basket of plants of Saxifraga ligulata. A silver Banksian medal was awarded to Mr. B. S. Williams, Upper Holloway, for large groups of well-grown Cyclamens of his special strain, and Primulas of the Chiswick Red, rubra violacea, fimbriata alba, and fimbriata rubra strains, all well grown, and with large handsome flowers. A bronze Banksian medal was awarded to Messrs. H. Cannell & Sons, Swanley, Kent, for half a dozen extremely large and vigorous specimens of Primulas Emperor, Swanley White, Swanley Purple, Old Fern-leaved White, Swanley Red, and The Queen. The plants were 18 inches or nearly 2 feet in diameter, exceedingly well grown, and profusely flowered. Some plants of a large-flowered purple variety named Mammoth were also shown, and a box of variously and brightly coloured Primula blooms. A fine group of double Primulas was sent from the Society's Chiswick Garden, comprising all the best of these varieties—Mrs. Barron, pure white; Earl of Beaconsfield, pink; Princess, white; and Marchioness of Exeter, white. A plant of the single Chiswick Purple, with very large richly coloured blooms, was also shown.

G. F. Wilson, Esq., Weybridge, exhibited a well-grown specimen of Odontoglossum roseum, with about a dozen spikes of its neat rosy flowers. Mr. H. James, Lower Norwood, sent a plant of the variegated Panax Victoria, which has the pinnules edged with white and sharply cut. Mr. Eckford, Boreatton Park, Shrewsbury, showed a plant of a purple variety of Primula sinensis named Perfection. The flowers were large but not of remarkable beauty. A vote of thanks was accorded to Mr. C. Ross, gardener to C. Eyre, Esq., Newbury, for five new Crotons, one a narrow-leaved form, a cross between Johannis and Weismanni, being graceful and brightly

coloured. *C. Eyrei* was also shown in good condition. Messrs. Stuart and Mein, Kelso, sent spikes of *Spiraea confusa*, a neat and pretty species, with umbels of diminutive white flowers. A cultural commendation was awarded to Mr. Mann, gardener to Sir J. W. E. Welby Gregory, Bart., M.P., Denton Manor, Grantham, for specimen heads of *Poinsettia pulcherrima*, with three and four branches, the bracts highly coloured. Mr. H. Bennett, Shepperton, sent a box of forty-eight blooms of *Chrysanthemum Princess Teek*, white, tinged at the base with purple, very neat and regular in form. A vote of thanks was accorded.

Two pans of *Sophranites grandiflora* were shown by Mr. Salter, gardener to J. Southgate, Esq., Streatham; the plants were bearing fourteen fine brightly coloured flowers, being exceedingly fine, the petals broad and dark scarlet in colour. Mr. Herbst, Kew Nursery, Richmond, was awarded a cultural commendation for some extremely well-grown potfuls of *Lily of the Valley*; each containing about sixteen fine spikes and large bells, pure white, and with strong green foliage. Votes of thanks were accorded to Messrs. F. Sander & Co., St. Albans, for plants of *Saccolabium giganteum* illustre, a species with white flowers spotted with purple, the lip being also purple, and *Odontoglossum Hrubyianum*, a species resembling *O. cirrhosum* in form of flower, but the sepals and petals are pure white; the lip being yellow at the base and streaked with chocolate. Mr. Todman, gardener to J. Cannell, Esq., Bushey Down, Tooting Common, sent flowers of seedling hybrid *China Azaleas* named *Snowflake* and *Bridal Wreath*, both pure white and very free. Mr. Merritt, gardener to Lord Dacre, was awarded a vote of thanks for heads of *Poinsettia pulcherrima plenissima*, full, but with narrow bracts. Mr. J. Sheppard, Wolverstone, Ipswich, showed spikes of *Salvia Sheppardi*, a cross between *S. splendens Branti* and *S. Heeri*, but not of remarkable merit. Mr. Heims, gardener to F. A. Philbrick, Esq., Q.C., Oldfields, Bickley, Kent, showed a plant of *Odontoglossum crispum guttatum* var., which has broad deep brown blotches on sepals, petals, and lip. Mr. W. Brockbank, Brookhurst, near Manchester, was awarded a cultural commendation for a specimen of *Helleborus niger angustifolius*, nearly 3 feet in diameter, and bearing over sixty blooms of good size and pure white, but they had suffered considerably in transit.

First-class certificates were awarded for the following plants:—

Cattleya Percivaliana (R. P. Percival, Esq., Birkdale, Southport, and Mr. Salter, gardener to J. Southgate, Esq., Streatham).—A new *Cattleya* which has recently attracted much attention. Flowers of moderate size, petals $2\frac{1}{2}$ inches long, 2 inches broad, delicate purplish mauve. The sepals are the same colour, but narrow, half an inch broad, $2\frac{1}{2}$ inches long. The lip is about 2 inches long by $1\frac{1}{2}$ broad, rich deep crimson edged with mauve.

Cypripedium Leeannum (Veitch).—An interesting and pretty hybrid between *C. insigne Maulei* and *C. Spicerianum*. The flower is intermediate in size; the dorsal sepal very similar to that of *C. Spicerianum*, but with a few purple dots down the centre and at the base, where there is also a tinge of green. The sepals and petals are greenish, with a tinge of reddish brown after the style of *C. insigne Maulei*, the staminode being very much like that of the latter, but not so large.

Dieffenbachia Jenmani (Veitch).—A species from British Guiana, with elliptical leaves, 3 to 4 inches broad and about 10 inches long, dark shining green with parallel blotches of white.

Laelia anceps Percivaliana (Percival).—A charming variety, very free; the plant shown having five spikes with three flowers each. The sepals and petals are nearly white with a faint tinge of purple, the lip being white edged with bright purple.

Cyclamen Crimson Beauty (H. Little, Esq.).—A remarkably fine variety, with neatly formed flowers of a uniform deep rich crimson and very freely produced.

SCIENTIFIC COMMITTEE.—Sir J. D. Hooker in the chair.

Sclerotia in Potatoes.—A communication was read from Mr. A. Stephen Wilson, expressing his views of the necessity of further examination of these bodies, which he proposes doing next season. He questioned the probability of Mr. Murray's experiments with nitric acid being decisive in showing that they are solely oxalate of lime. Mr. Murray remarked that the acid used was so excessively diluted that it could not have destroyed either protoplasm or starch if either had been present.

Impregnation of Potatoes through the Surface by Spores.—A letter from Mr. Plowright was read restating the fact that spores readily penetrate the epidermis of fresh tubers underground, but only through the eyes after drying. Mr. Murray observed that the question was not so much whether the earth could be penetrated, but whether it is usual for Potatoes to become injured in that way, and that the evidence for the disease reaching them by the haulm was certainly the common method.

Sifting Fungus Spores through Sand and Water.—Mr. W. G. Smith referred to some experiments he had made in reference to this subject. He said spores of the Potato fungus were not readily procurable in sufficiently large numbers wherewith to make satisfactory experiments, but spores belonging to the smut of corn (*Ustilago carbo*) he had in large quantities, and with these the experiments were made. *Ustilago* spores, being nearly black in colour, possessed a great advantage over the spores and zoospores of the Potato fungus, which were colourless.

Cylinders of glass were taken, each 8 inches long and half an inch in diameter; into one of these 6 inches of fine sand was placed, the bottom of the tube being first tied over with calico to prevent the sand escaping. A teaspoonful of water charged with *Ustilago* spores was then poured on to the top of the sand; in ten minutes the water all ran through, and on examination with the microscope as many spores were present in the water which had percolated through the 6 inches of sand as in the water which had not run through.

A second and similar cylinder was taken and charged with dry earth in fine powder. Water was then poured on the earth to make it quite compact, and more powdered earth and water placed in the tube till a compact 6-inch mass was presented. A spoonful of water charged with *Ustilago* spores was poured to the top. In two hours no water had run through, so the tube was left in a perpendicular position over a saucer all night. In the morning a part only of the water had run through, and this water was thickly charged with *Ustilago* spores. Mr. Smith said he was in the habit of filtering collodion through purified cotton wool, so that every particle

of dust and all minute atoms of grit might be retained in the wool, and he had never found the purified cotton wool fail. He therefore placed a plug of wool an inch deep in a third cylinder, and poured water charged with *Ustilago* spores on to the wool. In a short time most of the water had passed through, and there were as many spores, or nearly as many, in the filtered as in the unfiltered water.

In these experiments, as was to be expected, all the spores did not run through with the water in which they were originally held. Some of the spores together with a little water remained, but on the application of additional water (as must occur in the case of rain) all or nearly all the spores doubtlessly ran through. In the water which had passed through the earth a considerable number of spores belonging to two other fungi made their appearance. These must have been present in the earth. Mr. Smith said he had not the slightest wish to depreciate the value of Mr. Jensen's interesting full experiments, or to under-estimate the value of high moulding in Potatoes. He had merely challenged the experiments with sand, earth, and fungus spores. It had been proved, he said, that spores of a fungus (*Dactylium oogenum*) could find their way through the shells of fowls' eggs and grow on the membrane within the shell. In the face of a circumstance like this—and several others of a similar nature might be added, said Mr. Smith—the reports of spore-filtering through sand should not be received with too much credulity.

Professor Balfour remarked that spores—e.g., of *Penicillium*, contain fat, which renders them difficult to be wetted; while Professor Church added that carded cotton wool contains a half per cent. of fat, and it is only when treated with ether or boiling spirits of wine to remove this that it renders it easily permeable by water. If the wool has been thus treated water runs through with extraordinary rapidity.

Phylloxera in Victoria.—Mr. McLachlan alluded to a report made on this subject by a Committee of the Royal Society, when no phylloxera was discovered in the roots sent for examination; but, unfortunately, on examining some fresh material it is found to be undoubtedly present in some quantity. Not only was it in the living Vines, but in the roots left in the ground, showing the necessity of destroying by burning or drowning (as is done in England) the soil with the contained insects.

Coltsfoot in Flower.—Mr. McLachlan recorded the first blossom of this plant as seen by him on January 7th near Lewes. It blossomed on same day in 1882, and on January 12th, 1883.

Freesia sp.—Prof. Balfour exhibited a spray of small greenish yellow flowers. It was referred to Kew for identification.

Deoxidisation of Chlorophyll.—Prof. Church referred to a rediscovery by a French chemist of the possibility of restoring, not only the green colour to brown or oxidised chlorophyll, but also its characteristic absorption bands. He stated that about five years ago he discovered this process himself by mixing powdered zinc with boiling water and oxidised (brown) chlorophyll. It became after two or three days of a brilliant green. It had been extracted from Beetroot leaves.

Orchids from Out of Doors.—Mr. A. Smee exhibited a plant of *Odontoglossum Alexandrae* which had stood 8° of frost, but that species could not stand 11°. *O. Rossi* major, however, withstood 11° on December 13th; the plants were only protected by boughs.

LECTURE.—The Rev. G. Henslow first called attention to a *Panax* *Victoriae*. It had variegated foliage and with leaflets varying between pinnate and bipinnate. Comparing with *Aralia Sieboldi*, he pointed out how compound leaves, both of digitate and pinnate types, are formed from simple leaves by dividing them up into separate leaflets. The word "*panax*" was from the supposed virtues of *P. Schinseng* of China, the root of which was a panacea for evils, and would make men not only young but immortal. It had failed to do so in Europe. *P. quinquefolia* from North America was sometimes imported into China as a substitute. He next alluded to *Chimonanthus fragrans*, the Japanese Allspice, introduced in 1766 from China. This and the genus *Calycanthus*, called the Carolina Allspice, were the sole representatives of the order. The bark of the latter was sometimes used for Cinnamon. Mr. Henslow then remarked upon the fact that many plants, including Maples, Conifers, &c., had representative species in Japan and North America, and alluded to the speculations of geologists to account for the present distribution of such plants, and their descent from common forms, which probably existed in Miocene times, some of which appear to be those found at Oeningen and elsewhere in a fossilised state.

Crotons and Poinsettias were next taken to illustrate the order Euphorbiaceae, characterised in England by weeds like Spurge, but in tropical countries by trees and shrubs. He drew attention to the introduction of the Poinsettia in 1828, and figured in the "*Bot. Mag.*" vol. lxxiii., 3493. It was named after Mr. Poinsette, who discovered it in Mexico, who sent it to Charlestown, and from thence it came to Europe. Of Crotons, he mentioned the useful species—viz., *Croton Tiglium*, from the Indian Archipelago, whose seeds yielded the very acid Croton oil; *C. eleuteria*, from the Bahamas, which supplies the "cascarilla bark," containing bitter tonic and astringent qualities; *C. balsamiferum* of West Indies, from which a spirit is made called Eau de Mantes; and *C. lacciferum* of Ceylon, which furnishes a resin for varnishes. He alluded to the coloured and white foliage of these variegated plants, and explained how it was due to a want in the composition of the green chlorophyll, which is usually a compound substance of at least yellow chlorophyll and blue chlorophyll. In the case of the yellow leaves of the Croton the latter substance appeared to be wanting. In the white leaves of the *Panax* it was probably due to the extreme scarcity of chlorophyll grains.

The last subject for remark was a beautiful hybrid raised by Mr. Seden of Messrs. Veitch's establishment. It is called *C. Leeannum*, and received a first-class certificate. Its parents were *C. Spicerianum*, introduced in 1878, and *C. insigne Maulei*. It showed several intermediate characters; thus while *C. Spicerianum* had a corrugated purple and white "shield" (staminodium), that of *C. insigne* was smooth-edged and yellow-green. The hybrid shield had the colour of the latter, but the crimped edges of the former. Again, while the large upper petal is much spotted in *C. insigne*, not at all in *C. Spicerianum*, the hybrid is spotted, but to a much less extent than its parent. The slipper, however, was of a deeper red than is the case with either of the two species.

HARDY FRUIT GARDEN.

Birds and Buds.—Look to trees and bushes at once, and do all that is possible to keep off bullfinches and sparrows. In Christmas week we found pieces of buds scattered thickly under a May Duke Cherry tree which had suffered severely. Other Cherries and Plums had also been attacked by these troublesome birds. Gooseberries, too, had suffered slightly; as a temporary check as many trees as possible were immediately syringed with thin whitewash, and netting placed over all the bushes. Wire netting of sufficiently fine mesh to exclude small birds is decidedly best for bush-protection, and if kept permanently over them harm to bud or fruit could never happen. That this plan is desirable is proved by our own case. We had not lost a Gooseberry bud for eleven years, and had no thought of protection at this season of the year, but last year the bullfinches came in such numbers and with such persistency in spite of shooting that the crop suffered severely.

Planting and Training Raspberries.—In soil that is naturally suitable for fruit culture Raspberry culture resolves itself into careful planting, pruning, and training, and subsequently as the beds become old to surface dressings of manure; but in poor thin soil preparation must be made for each row by excavating trenches 3 feet wide and 18 inches deep, discarding the whole of the subsoil and filling the trench with a very rich compost of two-thirds of decayed vegetable matter or hotbed manure mixed with soil taken from the surface and laid aside as the trench is made. That this is necessary we have learnt to our cost, for we first tried trenching in a heavy dressing of manure in a poor soil, but the Raspberries never answered well, and we were obliged by dire necessity to resort to the trenches, which we did with complete success. At the planting each cane was shortened to 18 inches, and they were planted a foot apart along the centre of each trench, the rows being 5 feet apart, if space admits of it 6 feet apart is better. The 2 or 3 feet of poor soil between the trenches must be enriched the second winter after the planting precisely as if it were for another trench; the subsoil being taken away and the soil mixed with old manure. For training, a couple of wires, one 2 feet from the ground and the other 4 feet, strained to posts at each end of the row answer perfectly, the canes being tied to them erect, and cut off at 6 inches above the top wire. This height—4 feet 6 inches—we have found sufficient, the canes being laden with fruit from top to bottom. Higher canes throw so much shade that the lower part of the row has little or no fruit. We mention this matter because of the temptation to leave very strong growths longer than we advise, and it is not uncommon to see huge canes of 10 to 12 feet high before pruning.

Planting Fruit Trees.—Trenching land for fruit plantations is highly commendable, and it may be done now in any open weather. First do all necessary drainage, then trench two spits deep, breaking up the subsoil thoroughly, but simply turn the soil over upon it and bring no subsoil to the surface. The brick earth of North Kent so treated answers admirably for fruit culture. Planting follows the trenching in a fortnight or three weeks, but in cases of urgency we should not hesitate to plant immediately after the trenching, taking care subsequently to see that none of the trees become suspended upon the stakes, or the roots exposed or loosened in the soil as it settles. To do this thoroughly, examine the trees a month after planting, and again just before growth begins in spring. If the roots of newly planted trees are not closely embedded in the soil they will not grow; if they are left unfastened and become blown to and fro by the wind, or the soil about the roots becomes dry, the growth will be weakly and worthless, therefore stake and mulch at the time of planting. Apples, Pears, Plums, Cherries, Quinces, and Medlars are planted 20 feet apart if they are to become large standards or unpruned bushes, and there are three rows of Gooseberry or Currant bushes put between them and retained till crowded out by the trees. If closely pruned bush or pyramidal trees or Filberts are required, then 10 feet apart is sufficient, with one row of bush fruit between.

FRUIT-FORCING.

VINES.—*Early-fruiting Vines in Pots.*—Keep the house rather drier and warmer as the bunches come into flower. If the Vines are in a fermenting bed see that the heat does not decline, keeping it steady about the pots at 75°, encouraging the roots to find their way into the fermenting material or surrounding compost by applying weak tepid liquid manure. Tie down and stop young growth according to the space at command, and afterwards follow the extension system until the whole of the trellis is covered with foliage.

Early Vines.—When the buds on the Vines which have been suspended over fermenting materials have pushed freely from the rods these should be secured to the trellis. Disbudding must be performed by degrees, and see that the shoots are tied down before they touch the glass. Do not stop the laterals until sufficient growth has been obtained to secure an even supply of foliage all over the house, being careful, however, to prevent overcrowding, as it is important the principal foliage have full exposure to light and air. As the bunches draw out the temperature should be kept a little warmer, or 60° to 65° at night, with an increase of

5° to 10° by day; also keep the atmosphere a little drier, which has a tendency to prevent the bunches running into tendrils, as is sometimes the case when the wood of the Vines is badly ripened or the roots are in cold outside borders. If fermenting materials are used on outside borders the heat must not be allowed to decline, but by turning and adding fresh keep the temperature steady at 80° to 85°. The fermenting materials in the house should also be added to as occasion requires, replenishing with sweetened material, and with a gentle heat active feeding roots will be drawn up into the top-dressing of turf and crushed bones laid on in the autumn. Ventilate on all favourable occasions, being careful to avoid cold draughts and sudden depressions of temperature.

Succession Houses.—Where it is intended to have ripe Grapes early in June there must be no further delay in starting the Vines. All preparatory matters having been attended to, the inside borders must be given sufficient water at a temperature of 90° to bring the soil into a moist condition. A good bed of fermenting materials—Oak leaves and dung from the reserve heap made up inside the house—will help the Vines to break strongly and evenly. Strong young Vines when forced for the first time do not break regularly, and should be drawn down to a horizontal position until all the buds are fairly moving. Syringe the rods occasionally, doing so, however, sufficiently early in the afternoon to allow them to become dry before night. The temperature should range from 50° to 55° at night and by artificial means in the daytime, with an advance from sun heat to 60° or 65°.

Raising Vines from Eyes.—Select thoroughly ripened wood of medium strength for eyes, having them made and inserted in pots or sods without delay if intended for fruiting canes, placing in a bottom heat of 70° to 75°, and when growth takes place keep them near the glass, as it is important the wood be thoroughly solidified as made. Eyes intended to raise Vines for cutting back or planting need not be inserted or placed in heat until the middle of February.

FIGS.—*Early Trees in Pots.*—Assuming that well-ripened established trees were dressed and placed on brick pedestals with a body of fermenting Oak leaves placed round them, and the house closed early in December with a temperature of 50° at night and 55° by day, advancing 5° to 10° more from sun heat, the young fruit is now swelling, and the buds pushing into growth. The night temperature should be raised to 55°, with an increase of 10° to 15° by day from sun heat. Syringe twice a day, but always early in the afternoon, damping the floors well in the evening. Be careful not to have the bottom heat more than 70°. The roots will soon find their way into the fermenting material, and there do good service. Strive to secure short-jointed growth by admitting a little ventilation at the top of the house daily, giving sufficient fire heat to accomplish this at 65°, allowing the temperature to rise to 75° or a little more under bright sun, and close early in the afternoon, or between one and two o'clock.

PLANT HOUSES.

THE CONSERVATORY.—This house should be kept perfectly clean, for in any other condition it cannot be thoroughly enjoyed. It is wise to occasionally wash the glass, woodwork, and stages with warm water in which has been stirred a little soft soap. In many gardens at this season of the year flowers are scarce, but this need not be the case if previous directions have been attended to and care and judgment exercised in retarding or pushing forward plants that are in a backward state or coming forward too early. A good batch of dwarf Poinsettias should be grown in every garden where this structure has to be kept gay at the present time, as they take the place of scarlet Pelargoniums. Euphorbias are also useful and stand well, so does Centropogon Lucyanus. These associated freely and rising above Primulas, Cyclamens, Solanums, Hyacinths, Tulips, Cinerarias, Heaths, Rhododendrons, Azaleas, and others, have a charming appearance. Epacris at this season of the year, with their long slender stems of various-coloured flowers, stand well above dwarf plants. There is abundance of flowers now that will enable those who take a pride in their conservatories to make some of the most telling and effective arrangements possible at any season.

Tulips.—The early kinds that were placed thickly together in pans and boxes in August last as advised, and are now being forced, should, as they show the colour of their flowers, be lifted out. Early in the season if these bulbs are placed in pots and forced they often flower irregularly. By placing them in boxes those that show their flowers can be taken out and a number placed in 4, 5, or 6-inch pots, according to the size required, and thus even specimens are produced by a very simple system. The bulbs that are replanted should be kept well watered, and they will be found to last nearly as long as if they had been allowed to flower in the boxes without being disturbed. The single crowns of Lily of the Valley early in the season are treated in the same way, by which system only can full and regular pots of bloom be produced. This, if forced out in strong heat, must be gradually hardened before it is either cut or taken to the conservatory, and it will be found the sprays of bloom will last nearly double the length of time than if cut from a close frame or warm house.

Calanthes.—These beautiful Orchids are not used half so much in gardens for conservatories as they deserve to be. If the night temperature of the house can be kept on an average at 50° they will stand well when half developed and open the remainder of their flowers. If these plants when in flower are kept in a temperature 10° or 15° higher they will not last half so long. The flowers along their stem open quickly and are soon done, but this is not the case in the position we advise for them. Their deciduous character is a very great recommendation to them, because when grown in 5 and 6-inch pots for this purpose the pots can be hidden, and their long arching spikes of

flowers stand above other plants, and are thus shown to the greatest advantage. So many *Calanthes* of sorts cannot be grown where the conservatory has to be kept attractive during the winter months.

THE BEE-KEEPER.

NOTES ON BEES—PRACTICAL MANAGEMENT.

(Continued from page 520.)

TIMID BEE-KEEPERS.—Some bee-keepers are very much averse to opening hives oftener than they are compelled, on the principle that too much meddling is harmful; others, again, avoid interference with their bees because they are timid and cannot go about the task in that cool and quiet manner which is so requisite; in consequence it becomes to them a very disagreeable operation, and one to be avoided as much as possible. To advocate the system of spreading brood in spring with either of these classes of bee-keepers would be useless, as it requires frequent opening of the hive, and on this account would be highly objectionable to them.

One thing, however, is absolutely necessary—nine of the combs must be removed in autumn, and after being carefully wrapped up to protect them from moths, &c., kept indoors in a dry place for future use. In April of the following year, or as soon as the hive becomes populous and is working well, it requires enlarging; so if it is considered objectionable to do this gradually by spreading the brood as before mentioned the whole of the combs may be returned at one operation, and with very little disturbance, by pushing the nine frames upon which the bees have wintered, dividers and all, to one end of the hive. I insert the other nine combs, cover with the wood quilt, &c., and when all is arranged remove the divider and close up the frames. If a little smoke is used when lifting out the divider not a bee need escape, and the most timid manipulator will suffer no annoyance.

SECTION CRATES AND SUPERING, &c.—The general management of our hive in summer will be pretty well understood by those who have read what has already been written in former papers, so we need not occupy much space in describing it. But the subject of supering is such an important one to the apiarian, involving as it does the surplus honey for which he labours, that advanced bee-keepers are constantly desiring schemes which will assist in securing every advantage during the short time the honey season lasts.

We do not think the plan of storing section honey in the body of the hive will ever meet with favour from large producers, or be generally adopted. The objections to it are so many that it would take up too much space to enumerate them. Suffice it to say we have given it up, except for starting sections in early work and for completing unfinished ones in early autumn, and we find our opinion shared by all we have met with.

The proper place for supers is over the brood nest, where the warmth of the hive ascends and assists the bees in comb-building, and we have devised a section crate which is of great use in enabling us to overcome the difficulty so often experienced in inducing bees to enter supers early in the season. It is an effort to combine the advantages of the open crate, for convenience of handling and removal, with the superiority of the close crate over the other in conserving the heat at a time when this is so essential. All the sides are in two parts, hinged so that they can be let down when necessary. There is the usual half-inch space between the rows of sections, and three loose lids of half-inch stuff are used to cover frames and keep in the bees when the sections are not on.

When supering is decided on give one row only of sections (keeping the spaces to be occupied by the other two rows later, covered by the lids), and use no separators till the bees have taken possession and are working in the sections. If they enter at once it may be concluded that the hive is in good condition for supering, and the remaining two rows of sections should be given; the lids are then laid on the top of the section, and (except in hot weather) the quilts cover all to keep everything warm and snug. We always use the long-hole excluder zinc when supering.

For the timid and non-interfering bee-keeper already mentioned we need only say, Do not super till the first or second week in June unless the hive is very much crowded. Give the full crate of sections, and if honey is very abundant, a section crate may be set on alongside the first, as soon as combs are seen next the glass of those already on. When these combs are sealed over the whole crate may be removed for examination. If any of the sections are unfinished they may be given back to the bees to complete, or in a very good season the crate may be refilled and replaced on the hive.

We in common with all apiarians who are much among bees overhaul our sections at intervals, and removing such as are finished give empty ones instead.—W. B. C., Higher Bebington, Cheshire.

TO CORRESPONDENTS

To our Readers and Correspondents.—In consequence of the space occupied by the index to the last volume the publication of many valuable articles and interesting communications have to be postponed.

Rolling Lawns (F. J.).—No strict rule can be laid down on this subject. Some lawns, where the soil is naturally hard and porous, cannot be effectively rolled except after rain, while others of a wet and spongy nature are best rolled when moderately dry. Usually it is best to roll after rain in summer, but not in winter, especially if there are numerous wormcasts, because these adhere to the roller and are then shaken off more or less, spoiling the appearance of the grass. In rolling lawns in winter we always take advantage of fine days when the grass and wormcasts are dry, or nearly so, and the surface is kept smooth and clean.

Keeping Apples (Idem).—The fruit will keep quite as well on the uncovered shelves as on any soft material, provided it is handled carefully and placed in position gently to avoid even the slightest bruising. Much fruit is bruised by persons who have no idea of the fact at the time, because the injury is not visible at once; it, however, soon develops, the fruit being spoiled in appearance and impaired in quality. Apples and Pears should be handled and moved much more carefully than eggs, as being far more liable to injury; still, it is common to see the fruit poured out of baskets like so many Potatoes, while eggs are handled as if they were as tender as Apples.

Spray-Diffusers (Idem).—If you cannot find what you want at a chemist's or ironmonger's you might write to any of the dealers in horticultural implements who advertise in our columns or in the "Gardeners' Year-book," which is now being issued.

Staking Fruit Trees (D. Watts).—As a rule fruit trees ought to be secured to stakes as soon as planted, as they suffer materially if allowed to be twisted by the wind; but due consideration must be given to the condition of the soil. If it has been recently trenched and not settled the trees should be merely staged for a time, making them more secure in about a month. The roots should settle with the sinking of the soil, and they cannot do so if firmly secured to stakes before the soil becomes naturally consolidated. For this reason injury has often been done by securing trees closely to walls at the time of planting. They should only be lightly attached to the walls, then completing the nailing afterwards.

Pruning Roses (J. Tooting).—Although your Roses are starting into growth freely you had better not prune them. Even if they grow 3 or 4 inches near the extremities of the shoots, it is not likely that the lower buds will start, but the sap will flow past them into the outlets already provided; but if you remove the growing portions it will then be directed to the remaining buds, which cannot under its pressure long remain dormant if the weather continues mild.

Double Primulas (Idem).—Two of the best varieties now flowering at Chiswick are Lord Beaconsfield, carmine, and Marchioness of Exeter, blush white. You may grow these, also the old double white, which affords an abundance of flowers for cutting.

Mildew Composition (G. B.).—We cannot suggest a better method for testing the efficacy of your composition than in the summer, when mildew is prevalent on Vines, Peaches, and Roses, to offer to send a sample to cultivators who find it difficult to eradicate the pest. Will it destroy the Orange mildew on Roses? Although, as you commendably say, your "greatest desire is to benefit others," you are certainly entitled to some "small remuneration" if the composition proves more efficacious than others in the market, and this can only be determined by trials by different persons in the manner suggested.

Black Currants Buds "Knotted" (T. W., & Stoneleigh).—The condition of the buds is due to the presence of insects, and when these are numerous the bushes are practically ruined. We will refer to this subject more fully in an early issue, but in the meantime we fear there is no better remedy than cutting down the tree and burning the branches. The safe course, however, is to obtain healthy young trees and plant them as far as possible from those that are "knotted."

Propagating Indianrubber Plants (T. Butler).—The tops of plants 6 inches long, the lower pair of leaves removed and the stems inserted firmly in small pots of very sandy soil and plunged in a bottom heat of 90° in a warm propagating case, will, if kept constantly moist, emit roots and soon make attractive plants. Expert propagators raise a plant from every developed leaf. The leaves are scooped out of the stem so that the bud in the axil is secured. Each leaf is then secured to a stick and coiled round it as if coiling a sugar paper, and in that form loosely secured. Small pots are filled with nearly pure sand and watered, then the base of the leaf is pressed in it, covering the stalk, the stick which extends an inch or two below this holding the coiled leaf firmly. Quite small pots are employed, one leaf being inserted in the centre of each. These are plunged as before in a warm close case, and the soil and atmosphere kept constantly moist, yet not excessively so, this being governed by slight ventilation for a short time early in the morning. In due time the leafstalks callus and roots form; then the dormant bud elongates and a plant is produced. The hundreds of dwarf plants sold in Covent Garden Market are propagated in this manner; but it is no use attempting it without a brisk and regular heat, and a suitable frame or case.

Asplenium Ruta-muraria (A.).—This Fern thrives best in the crevices of limestone rocks where the atmosphere is moist. It succeeds in damp walls where there is lime either in the stone or mortar employed. A suitable compost for growing it in pots is crushed lime rubbish three parts with

one part each of peat and loam. It requires abundance of air, and does not succeed in close frames.

Ville's System of Manuring (*Paideia*).—The author named advocates the employment of chemical or artificial manures instead of ordinary farmyard manure, but you will find the whole fully explained in Crooke's translation of Ville's work on artificial manures, published by Longmans, Green & Co. We do not understand the second question in the form you state it. Cannot you obtain the information required from the science schools you appear to be connected with?

Materials for Vine Border (*Old Subscriber*).—You appear to have all the materials you need, as, although you do not name it, we presume you have a supply of good fresh loam of medium texture; and the ashes you name are, we presume, wood ashes, as they should be, and not the remains of coal. You mention "improving" a Vine border, and then ask when the border should be "made." This implies that you intend taking up the Vines, removing all the soil, adding fresh, and then replanting. You may do this now. Does not your gardener understand the work? If he does not we will readily aid you and him if you can enable us to understand the actual condition of the Vine and border.

Ivy for Growing under Trees (*Idem*).—Both the common large-leaved Irish Ivy that is usually employed for covering buildings, and the small English Ivy that grows wild in woods and covers the stems of trees, will answer your purpose, and you may plant the one you prefer. It is advisable to get healthy well-rooted plants, and dig and enrich the soil before planting to insure a free growth and quick covering of the now bare space.

Shading Melons (*J. T. S.*).—The necessity for shading Melons has rarely occurred with us, never, perhaps, except a few days of very dull weather are followed by a sudden outburst of hot sun, and then the shade afforded is of the lightest, such as a covering of hexagon netting; but we are always careful that the plants are well supplied with water, and that by timely thinning stout thinly disposed leaves are insured that do not flag during the brightest weather. Early morning ventilation, too, is always practised; in fact, the pits are not entirely closed at night during hot weather. Melons need shade occasionally when the glass is faulty and when the plants are grown in light soil; with strong soil, good glass, and good management the necessity for shading is reduced to a minimum. Where much shading is resorted to the fruit is seldom of high quality. Notes on Mistletoe propagation will shortly appear in our columns.

Relative Value of Manures (*W. R.*).—It is impossible for us or anyone to answer your questions categorically. An analytical chemist could tell you the constituents of any samples he examined, but farmyard manures differ very materially, and the term "average," as applied to them, is meaningless for all practical purposes. We give the analysis of Boussingault of good yard dung.

	Fresh.	Dry.
Carbon	74	358
Hydrogen	9	42
Oxygen	53	258
Nitrogen	4	20
Inorganic matter	67	322
Water	793	—
	1000	1000

The composition of the inorganic part of such manure, like that of the organic, varies considerably. The following shows the composition of 10,000 parts of the inorganic matter in yard dung (Richardson):—Potash, 322; soda, 273; lime, 34; magnesia, 26; sulphuric acid, 327; chlorine, 315; soluble silica, 2705; phosphate of lime, 711; phosphate of magnesia, 226; phosphate of iron, 468; phosphate of manganese, trace; phosphate of alumina, (?) trace; carbonate of lime, 934; carbonate of magnesia, 163; sand, 3099; alkali and loss, 397; total, 10,000. Soot also varies greatly. The constituents of a good sample are—charcoal, 371; salts of ammonia, 426; salts of potash and soda, 24; oxide of iron, 50; silica, 65; alumina, 31; sulphate of lime, 31; carbonate of magnesia, 2. Johnston, in his "Lectures on Agricultural Chemistry," thus refers to the variability of soot:—"The earthy substances which the soot contains are chiefly derived from the walls of the chimney and from the ash of the coal, part of which is carried up the chimney by the draught. These, therefore, must be variable, being largest in quantity where the draught is strongest, and where the earthy matter or ash in the coal is the greatest. The quantity of gypsum present depends upon the sulphur contained in the coal; that which is freest from sulphur will give a soot containing the least gypsum. The ammonia and the brown soluble substance containing nitrogen will vary with the quantity of nitrogen contained in the coal and with certain other causes, so that the composition of different samples of soot may be very unlike, and their influence upon vegetation therefore very unequal. The consequence of this must be, that the results obtained in one spot, or upon one crop, do not indicate the precise effect which another specimen of soot will produce in another locality, and upon another crop even of the same kind. And thus it happens that the use of soot prevails more, and is attended with more beneficial effects, in some districts than in others." The relative value of manures for practical purposes also depends greatly on the soil to which they are applied and the crops that are being grown; and you can only ascertain by experiment what kinds are the most effective and economical in your case. There is no other method of determining this so well. The market price of soot varies in different localities. We know of no book such as will exactly meet your expectation. Ville's work on artificial manures would probably be interesting to you; whether it would be useful depends on yourself.

Names of Fruits (*E. J. Lowe*).—Herefordshire Costard. (*T. H. A.*).—1, Ravelston Pippin; 2, Stirling Castle. (*Dorset*).—Golden Noble. You will find Melon culture in the "Manual on Kitchen Gardening," which you can have free by post by sending 4½d. in stamps to this office. (*Colville Browne*).—1, is not Round Winter Nonesuch, name not known; 2, Winter Majetin; 3, Pear perfectly worthless and name not known; 4, Vicar of Winkfield. Seedling Apple (*E. Charlton*).—Your Apple is of good flavour and handsome appearance, and though it is worth your keeping, it does not possess merit sufficient to warrant its being put into commerce.

Names of Plants (*A. H.*).—We cannot name two such diminutive fragments of plants as those you sent. Better examples in flower would be readily determined.

COVENT GARDEN MARKET.—JANUARY 9TH.

BUSINESS still keeps quiet, and prices have given way again. Kent Cobs easier.

NEW AND IMPROVED AGRICULTURAL MACHINERY.

IN resuming this important subject we find various objects that were exhibited at the Islington Hall meeting of the Smithfield Club which demand attention. These must prove interesting to the farmer not only on account of their value for agricultural purposes, but also for the great ingenuity displayed in providing the most useful and at the same time the most effectual implements, calculated, not only to save and economise labour, but to afford the best methods for assisting and promoting new objects of profit in the profession of farming. Numbers of these implements are no doubt extremely valuable, but are also suggestive of objects and improvements as yet to be forthcoming in the future; and when we look back only a few years it must to every thoughtful mind be matter of astonishment that many of the recent discoveries had lain so long unavailable.

We find illustrated and noticed in *Bell's Messenger* various useful implements, some quite new, others improved. Amongst the former must be classed as a speciality exhibited by Mr. Thomas Corbett, of the Perseverance Iron Works, Shrewsbury, an implement which has not, perhaps, received the attention from English farmers which it deserves. The original and peculiar construction of the revolving mould board plough should induce practical farmers to give it a fair trial of its merits in the field, upon suitable land and under circumstances for which it is recommended. The revolving mould board is simply a wheel or disc, with concave and convex surfaces, the concave being presented to the furrow at a proper angle from the face on the land side. By a simple contrivance the mould board is adjusted to any required pitch, enabling the ploughman to adapt it at will to the varied requirements of the soil to be worked. A plough, therefore, which will make possible a more thorough tillage at a great saving of time and expense, ought to be doubly acceptable to every farmer. Believing that the patent revolving mould board plough possesses this merit in a very high degree, Mr. Corbett confidently submits its claims to the careful examination of the public. It is stated to possess the following advantages:—1st, It has a very superior pulverising power. Stubble land ploughed with this plough requires no harrowing. 2nd, It does not, in any circumstance, compress, smooth, and glaze the surface of the land slice; an advantage in wet or clayey soils. 3rd, By reason of its adjustable mould board it is adapted to either turf or stubble. In combination with the skim coulter, the sod may be thoroughly inverted and buried, so as to leave no

visible trace of its existence. This fact, and the high degree of pulverisation effected by the peculiar action of the revolving mould board, makes the subsequent planting and tilling of greensward as unobstructed and easy as is that of free or stubble land. 4th, With the revolving mould board plough clogging is an impossibility. For this and other reasons it turns under stubble and coarse manure more effectually, and distributes them more evenly than the common plough. 5th, The diminished friction lightens the draft; two horses doing with ease on heavy land the work of four with the ordinary plough, and the saving in draft is important. 6th, By removing the mould board it is converted into an excellent subsoil plough. Now these are a list of extremely valuable points, especially on lea ground or in case of ploughing-in green crops of any kind as manure, and we think worth the consideration of the home farmer under varying conditions of the land and season.

Another exhibit at Islington Hall by Messrs. Ransome, Head & Co., of the Orwell Works, Ipswich, is called "The Garden Plough," from the work it does being similar to that of the spade, is a most valuable implement, and is likely to be largely adopted. It is made with short beam and handles so as to take up but little room at the headlands when used for fruit culture, and is fitted with a wide share and deep drilled iron mould board, with a tail piece which breaks the furrow as it is turned. When used for farm work it can be fitted with a large skim-coulter for effectually burying the grass or twitch. We can readily believe in the effect of the turn furrow with tail piece, for we had many years ago one of our ordinary ploughs fitted by the smith with a kind of cutting knife fixed at the heel of the turn furrow, and it answered a good purpose, for when the land was kind and workable it left the land in a state fit for seeding without any harrowing at all.

We must now call attention to a patent yealming machine by Mr. Maynard, and when attached to his combined chaff engine was one of the most attractive novelties in the Agricultural Hall. In using it, a man pitches the hay or straw on to an elevating endless rake, which draws up the material to the yealming apparatus which straightens it for the knife of the chaff-cutter. It is a well-known fact that unless the straw is properly yealmed by hand before it goes into the feeding box a large portion of it goes in sideways and passes out of the engine as cavings. Maynard's mechanical yealming machine does the work better and more regularly than is done by hand, so that there is a gain apart from the great saving of manual labour, consequently the general advantage is immense, because farmers see the practical benefit of the combination. There were two other machines exhibited in the Agricultural Hall besides chaff-cutters that require Maynard's yealming machine—viz., Messrs. Clayton and Shuttleworth's chaff engine attached to their three hing machine, and Messrs. J. & F. Howard's straw-trussing machine. In the former case the yealmer would be placed between the straw shakers and chaff-cutter, and in the latter between the threshing machine and trussing or binding machine, and by combining Maynard's yealming machine, as shown in the hall, with Messrs. Howard's trussing machine, hay or long grass may be bound up in trusses as fast as it can be fed into the combined machine

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—As soon as the winter fallow-ploughing is completed horses will be employed in carting farmyard and box dung to the heap for the early root crops, such as Mangold, Potatoes, Cabbages, &c.; but in doing this the carts should be drawn up on the heap during accumulation in order to prevent its too great fermentation; for when it is cast into heap, instead of the carts being continuously drawn on the heap to tip their loads, it is apt to heat and lose a considerable portion of its value. There is, however, another way of disposing of the farmyard and box manure by laying it out and spreading immediately on the young Clover plants; and the fresher and newer it is, if properly made and mixed, the better, because if the straw is not entirely rotted down it will when spread fertilise the land as soon as rain occurs. The straw portion will overlap the Clover plants and to a certain extent preserve them from frost and snow, from which the roots often suffer, especially if the foliage on the crowns of the plants has been eaten down close by hungry sheep, which is too often the case, and the plants will frequently die. The carting of earth for making composts mixed with dung may now be done in readiness for application to pasture and parklands; and the pastures, which are either fed by dairy cows or mown for hay, should, to keep up fertility, receive in alternate years 3 cwt of bone superphosphate and 20 tons of compost per acre, the time for application of the superphosphate being the month of February, and the dung compost in dry weather in the winter months or immediately after the hay crop has been removed. Threshing corn of various kinds may now be done, so that any horse labour required for delivery either of corn or straw, may be done in the least busy period of the year. The corn which is intended for seed or for horse provender or cattle-feeding may be stored

in the granary, and the straw as fast as threshed should be carefully stacked, or any portion required for the thatching of buildings or cottages may be used for that purpose immediately, for the thatching done in the winter months will generally settle down closer and last longer than that which is laid on during the summer.

Hand Labour.—As this is the period when the underwood in the coppices is being cut, all wood required on the farm should be preserved. Spar wood for the thatcher will be required, also all the white and black thorns should be reserved just as they are cut, for carting away to those fields and roadsides where dead hedges are to be made, as this is particularly necessary on the open hill farms on the chalk or limestone hills. This being the period for executing this work a certain portion of the underwood either from the coppices or wide rows between the fields, the wood adapted for stakes, &c., should be carefully selected and carted to where it will be required, so that the horses may not be called away from tillage work during any busy period. Banking and ditching, too, in the enclosed districts of strong flat-lying soils, will now be going on, but let the home farmer bear in mind that it is frequently better to do away with banks and ditches than to repair or make them new. Draining, too, should be done where it has previously been carefully set out; but in general it is better to set out the work of draining in the first dry weather which occurs in the month of March or April, as it is easily seen at that time which are the parts most requiring to be drained.

Live Stock.—As roots are an abundant crop this year there is every reason why the horses at work on the farm, or the young animals also of one or two years old, should be allowed a small portion of them with their dry food, for our experience has taught us that the plan frequently adopted by farmers to only allow dry fodder and corn for their working horses during the winter is a mistake. We find that a moderate allowance of Swedish Turnips, Carrots, or Mangold, say from 10 lbs. to 14 lbs per day, will prove a great benefit to hard-worked farm horses or colts in the straw yard; it supports the constitution better, and we believe that various animals become incapable years sooner when kept on all dry food in the winter months, for the change is too great in the autumn from green fodder to corn and dry fodder, and the same in the spring when the change is suddenly made from all dry fodder to luxuriant Trifolium. Cattle in the boxes should now be prepared for the butcher according to size and forwardness, pushing on the largest bullocks for slaughter previous to the 1st of May, and reserving the smaller animals and lightest weights to be sold during the summer months, feeding the animals so as to be ready in succession for slaughter at the time required.

OUR LETTER BOX.

Unproductive Land (H. S. E.).—You have four acres of land, about one-half being very dry and the other half very wet; it is probable that the latter requires draining, and that it is made wet by springs from the higher gravelly land. If this is so, draining should be done, the springs being cut off by a drain 4 feet deep and pipe tiles laid between the light land and heavy. It is more than probable that the heavy land requires draining also. This should be done by drains 20 feet apart and 3 feet deep, with 2-inch pipe tiles laid down the incline and leading into a main drain 15 feet from the ditch instead of each drain having an outlet. As this land has been unproductive it is perhaps very foul with couch, and, if so, it should have a summer fallow instead of being cropped; while if the land is sour it requires chalk or lime. If it is clean it may be drained immediately, and then manured and sown with Oats on the strong part and Barley on the light part, and both seeded to Clover. If it is foul and fallowed it may be well manured in the autumn and sown with Wheat.

ROYAL AGRICULTURAL BENEVOLENT INSTITUTION.—The monthly meeting of the Council of this Society was held at their offices, 26, Charles Street, St. James's, on Tuesday, the 1st inst., Mr. John Marten in the chair. The Secretary stated that there were at present on the books of the Society 611 pensioners, eight having died during the past three months; and that since the last meeting of the Council £3324 had been received from subscriptions and other sources. Cheques amounting to £3385 for quarterly pensions and current expenses were drawn.

PHYLLOXERA.

IT gives me very great pleasure to be able to say that this insect does not now appear to me such a formidable foe—at least, to English cultivators of the Vine—as it has been hitherto; nor does it now seem such a hopeless task to extirpate it from our vineries without sacrificing the Vines as it previously did. I would not wish it to be understood that this, the worst enemy the gardener has, should be underrated nor indifferently regarded; on the contrary, I fully believe it will still require the strictest precautions, the utmost vigilance, the earnest and combined efforts of every cultivator, whether in the vinery or in the open garden, to stay its progress.

As to stamping it out—well, I never yet believed in the impossible creed, and will therefore say no more on that head, but would rather urge upon every individual who cultivates a Vine, whether in a pot for sale or in the well-appointed vinery or on the cottage wall, not to harbour this insect thoughtlessly nor ignorantly, but to make himself acquainted with its nature and economy as soon as possible, and when they find it to destroy it instantly. Immediate, determined, and combined action would certainly go a long way towards stamping it out; but while it is permitted to remain undisturbed in our vineries, to multiply and pass through its various stages, and to eventually assume its winged form, whereby it may be wafted to new stations to form fresh colonies, extermination is indeed a vain hope.

As to the individual who has ventured to designate the wholesome fears which most gardeners entertain of this pest as a needless sensational scare, the worst I wish him is that he may never from personal experience of its terrible powers of destruction have cause to repent the use of such language. But after the numerous instances of the serious havoc it has caused in this country during the last twenty years, which attacks will necessarily increase while such heedlessness is shown, thoughtless expressions should not, I think, be allowed to pass without reproof. We know that in everyday life, as the most simple and trivial actions of the least of us may influence someone either for good or the reverse, so also from our attempts as scribes similar results may accrue.

In attempting to exterminate this insect from our vineries it will, I think, be requisite that the present system of cultivation should be considerably modified, also that somewhat greater preparatory arrangements and expenses should be incurred than have hitherto been thought necessary. This insect is so minute as to be almost invisible in its migrations. It attacks that part of the Vine more especially which is the least easy of inspection, and where it is the most difficult to detect and destroy. It increases in numbers so rapidly and consumes the roots so voraciously that its presence also may not be suspected by the keenest observer till considerable injury has been effected, even to such extent as to seriously impair in a few months the vitality of the strongest Vine. It therefore becomes imperatively necessary that, if possible, some simple and effective

antidote should be employed which, by its frequent periodical use, will act not only as a safe and convenient preventive, but also as an effective destructive agent.

Should annual inspection of the borders and roots be instituted it can only be done with safety at the fall of the leaf, and then only partially, nor without the Vine receiving at least a slight check, nor can it be accomplished without incurring considerable expense in labour. But what is far worse is the damage the insect is capable of inflicting during this interval of time, and when found the Vines, borders, and everything else pertaining thereto must, under existing circumstances, be swept clean out and burnt, so as to effect a perfect riddance of the pest. New borders must then be made and fresh Vines established with the fervent yet sometimes fruitless hope that it will not again appear.

This loss of time, these difficulties and expensive operations, tend to show how invaluable must be a simple and efficient preventive; they also tend to justify most conclusively an increased preparatory expense which shall secure immunity from its attack. One of these agents, which in some of the continental vineyards has, we are informed, been of some value, is sulpho-carbolate of potash. How frequently, or in what particular quantities it has been used, I do not know, but we are informed it has been applied as a surface dressing, and either watered-in immediately or else been permitted to remain on the surface to be washed down to the roots by rain, where it is said to instantly destroy the insects and also to act as a fertiliser to the Vines. I regret to say that my experience with it as a destructive agent has not been very satisfactory. I can scarcely believe that it was not applied in sufficient quantity, but whether the water being allowed to remain in the vessels with the compound tended to counteract and neutralise it I cannot say. As will be seen below, it had no appreciable effect in destroying the insects, and, as far as my experiments went, they tended to show that it is of little value for this purpose.

Pieces of Vine root from 6 to 18 inches in length, and covered with phylloxera, were placed in five different vessels, each of which was numbered. The roots were covered with loam, water was then introduced, and afterwards the sulpho-carbolate of potash was added in quantities as follows:—

Vessel.	Gallons of Water.	Sulpho-carbolate of Potash.
No. 1	1	1 oz.
No. 2	1	2 ozs.
No. 3	1	3 ozs.
No. 4	1	4 ozs.
No. 5	1	pure soft water only.

This was done on November 12th, and after twenty-four hours' submersion the roots and insects were carefully examined under a magnifying power of 70 diameters, or 4900 times superficially, when nearly every insect was found to be alive. Being otherwise engaged at this time, I could not examine them again till the 17th, five days after submersion, when all were found to be dead, not only in the vessels which contained the potash, but in that which contained only pure water.

On November 19th I again prepared the vessels and roots precisely as before, with the exception that different and greater quantities of potash were used, as follows:—

Vessel.	Gallons of Water.	Sulpho-carbolate of Potash.
No. 1	1	2 ozs.
No. 2	1	3 ozs.
No. 3	1	4 ozs.
No. 4	1	8 ozs.
No. 5	1	pure soft water only.

Pieces of root taken from each vessel were examined under the same power as previously used, after twelve hours' submersion, when, in each instance, the insects were found to be alive. On the 20th they were again examined after thirty-six hours' immersion, when from 50 to 60 per cent. were found alive in each vessel.

Again, on the 21st, after sixty hours' immersion, they were examined, when from 5 to 10 per cent. in each vessel were still found to be alive, but their movements at this time were so slow and feeble as scarcely to be perceptible. On the 22nd, after eighty-four hours' immersion, they were again tested, when all were found to be quite dead, in the pure water as well as that which was mixed with potash, and, in many instances, the insects were partially decomposed and required but the merest touch with a needle to fall to pieces. These experiments proved most conclusively two things—first, that the application of half a pound of sulpho-carbolic acid of potash dissolved in a gallon of water will not instantly destroy this pest, nor did its presence in the water appear to exercise any decided effect on the insect. As the potash was obtained specially for me through a first-class wholesale chemist, and as the purpose for which it was required was made known to them at the time of ordering, and the cost—8s. per lb., I have every reason to suppose it was genuine. If the proprietors of the continental vineyards pay the same price, and apply it in the same proportion as I did, I fear, even if the results were satisfactory, its free use would prove far too expensive.

These experiments also proved most clearly that eighty-four hours' complete submersion, even in pure water and loam, will effectually destroy it. Hence, this simple and comparatively inexpensive method seems to be, at any rate in England where the space occupied by the Vine borders is necessarily limited, to be deserving of consideration. To those who are about to erect new vineries or renew old borders I would particularly recommend tank borders, where the roots may be conveniently and completely submerged for four or even six days every spring just as the buds begin to swell, and again for the same length of time each autumn when their growth is completed. I say six days, because it would undoubtedly take a longer time for a Vine border to become thoroughly saturated than was the case with the soil covering the roots in the vessels used; nor do I think complete submersion of the border for six days at the two periods mentioned would prove injurious to the Vines, provided thoroughly efficient drainage be secured afterwards.

Lest the mention of "tank Vine borders" should alarm some of your timorous readers, I will endeavour to show that they are neither such costly nor such inconvenient structures as would at first appear, and certainly not so much so as to prevent their erection for this special purpose. If a tank border will afford a safe means of security against the attacks of phylloxera, and I firmly believe it will, its first and only cost would prove much less than that occasioned by a visit from this unwelcome visitor into an ordinary border. It is not an unusual practice, nor is it an unnecessary one in low-lying positions, or where the subsoil is at all retentive of moisture, to concrete the bottom of a Vine border, and where this is done it is but the addition of four upright walls 4 feet 6 inches high, and 6 inches wide, built with the same materials and rendered with cement and fine sand, and the tank is complete.

As I do not believe in preaching one doctrine and practising another, I will briefly describe the steps we have already taken in this direction. Having last autumn discovered phylloxera in three old vineries in the outside as well as inside borders, and having first obtained the permission of my noble employers, it was decided to make a clean sweep by removing every particle in which it was possible for the insects to lodge. After fumigation, painting, and general cleansing, it was determined, after the results of the experiments already mentioned, to erect tanks. These houses having formerly been used for growing Pines, the tanners' bark pits in them offered favourable facilities for their erection, the four walls forming the pits having only to be faced with cement as well as the base, and the tanks were completed. Ample provision for drainage was provided by giving a sharp fall to the bottom of the border to the lower side. Two-inch pipes were then inserted through the wall at

the lowest points, and neatly fitted with modern plugs on the outside, so as to be conveniently adjusted. The drainage consists of 9 inches of brickbats laid level on the top, over this 4 inches of coarse gravel or stones about 2 inches cube; this is made perfectly level and rammed down firm, then 3 inches of coarse cinders and slag; this is also rammed quite level as before, and finally 3 inches of coal ashes also rolled down perfectly firm and even. I need scarcely say that this will remain porous for any reasonable length of time. The soil rests on this, as I do not like the practice of inverted turves on the bottom, simply because they form, after the grass and fibre is decayed, a bad means for quick drainage. The borders being small, they are made of good lasting materials—i.e., good sandy loam with a small admixture of bones, lime scraps, and a portion of the old border in the form of burnt earth and charcoal; this being dry it is placed not lightly, but trodden down firmly to a depth of 2 feet 9 inches, allowing 6 inches for water space on the top.

The Vines will be planted in the spring, and as there is very little vegetable matter in these borders I purpose supplying the missing ingredients by means of a hose from a tank, into which runs the liquid from the decaying vegetable heap and stable yard. Fortunately the proper elevation of the heating apparatus enables me to warm this water to any required temperature by admitting at will into the supply pipe a sufficiency of hot water. Similar means also exist for the admission of clear water when required. By these arrangements I hope to bid defiance to the phylloxera, which I need scarcely say has caused me some anxiety and trouble. I have, however, the satisfaction of knowing that the labour in these vineries in future will be greatly lessened by the tank system, which to my mind possesses many advantages, irrespective of the great one, of being phylloxera-proof.

So out of evil sometimes comes good. In examining specimens of phylloxera the other day through a magnifying power of 300 diameters, I observed that many of them were nearly covered with reddish-coloured, beetle-like parasites, plainly showing that even these mites in creation are in their turn food for others, even smaller still.

"Big fleas have little fleas on their backs to bite 'em,
Little fleas have lesser fleas, and so *ad infinitum*."

—T. CHALLIS.

PEA CULTURE.

IN preparing ground for Peas it is very important that it should be deeply dug or trenched, and if poor a plentiful supply of manure should be given; but in gardens which have been a long time under good cultivation it is possible to make the ground too rich, and when this happens the Peas run up to a great height and make long jointed growths which are not fruitful. On very hot dry land it is a good plan to prepare trenches in the same way as for Celery. These trenches should be left partly open after the Peas are sown. By thus leaving the trenches a good opportunity is afforded for drenching the soil with liquid manure should the weather be such as to render this necessary. The distance between the rows will depend on the height of the sorts grown. It is better to give tall growers from 6 to 10 feet between them, and to grow a crop such as Cauliflowers or Lettuces between than to crowd them.

I do not think anything is gained by sowing too early. I have found the month of February quite early enough for this low-lying and somewhat cold district, but I would advise a good quantity to be sown at one time for the first two or three sowings, after which I make a practice of sowing every week, in quantity according to the demand, up till the end of June. Having got the earliest sowing fairly up they must be carefully watched, as if left unprotected the sparrows will soon make short work of them. A very simple though good plan is to place a few spruce boughs on each side of the rows in addition to the Pea sticks. Around these run some cotton or pieces of old garden netting. The sparrows do not like the look of this, though in time they will get used to it and will make their way to the young Peas if not well looked after.

One of the most important points in growing Peas really well is in keeping them sufficiently moist at the roots, and

this important matter must not be delayed till the crop is suffering by the want of water, but must be seen to as soon as a fair start is made. One thorough watering should suffice, after which a mulching should be given. If half-decayed manure can be spared so much the better, but failing this something must be found, if it is only a few handfuls of leaves, fern, or straw; in fact, anything to retain the moisture.

In addition to the varieties mentioned I have found the following give excellent results—Gladiator, Marvel, Criterion, Telegraph, Telephone, Laxton's Supreme, Vetch's Perfection, Emperor of the Marrows, and Ne Plus Ultra. I have grown many others, but at present prefer the above to meet the peculiarities of our climate.—G. MERRITT, *Welwyn*.

PLANTING LILIUMS IN SHRUB AND FLOWER BORDERS.

MR. LUCKHURST has given us some very suggestive notes on the above subject on page 556, last volume—especially interesting being those on his success during the past season with *Lilium auratum*, the queen of Lilies in the open borders. Most of us are familiar with this grand species, and also experience but little difficulty in its culture grown in pots; but to successfully establish bulbs in the open border and maintain them in health for a number of years is no easy task. Many have tried to do so, but have failed to induce them to thrive satisfactorily after the first season, although every means as regards soil and situation had been used to that effect.

My employer is an ardent admirer of Liliams, especially *L. auratum*, and for years previous to my taking charge he had tried to get bulbs of the latter established, but to no effect. For instance, a clump of two dozen fine bulbs of *L. auratum* were planted in well-prepared soil and good situation a couple of years ago. The first year every bulb flowered well, but in the second only half a dozen threw up flowering stems, the blooms of which were very inferior in every way. More than half of the bulbs, too, had perished. We have, however, notwithstanding previous failures, resolved to give the latter species another trial. As I have previously stated in former notes on this subject in the Journal, we procured a number of fine imported bulbs and potted them early in the year. In May these were planted out in groups on the rockwork in sheltered portions of the garden, and after flowering allowed to remain there, hoping to establish them. I have to-day examined the bulbs and find they are in good condition, so hope to obtain better results next year. It certainly seems strange that in some instances *L. auratum* is found to thrive and flower for years in the open border, whilst in others inevitable failures occur. In a small garden not far from here I saw some fine clumps in flower during the summer, and these had been growing and flowering for years in a *Rhododendron* bed.

Again, that skilful cultivator of hardy plants, Mr. Wolley Dod, seems to have discovered the secret of their successful cultivation, for on referring to page 215 of vol. v. of the Journal, I find an able article by him on the culture of *Lilium auratum* in the open border. After discussing the superiority of English-grown over imported bulbs, the greater per-centages of failures in the open borders *versus* pots, and his disapproval of the plan of potting the bulbs previous to planting them out later on, he having planted bulbs when the ground was frozen to a depth of several inches; taking care, however, to remove all frozen soil and use such as was not around the bulbs. He gives the details of his observations and experience as follows:—"As regards the position in the garden in which to plant *L. auratum*, we are often told that they like shade, but the more I see of them the more inclined I am to think that in the English climate it is not easy for them to have too much sun. Shelter, no doubt, is good, and vacant places in *Rhododendron* beds, where the young growth is sheltered from parching winds and spring frosts, are good situations to plant them; but overhanging trees, which encourage damp and cause the air to stagnate, are favourable to a disease called 'spot,' which destroys the flowering of these Lilies. After trying every part of my garden I find that they do best in some exposed beds with 3 feet of moderately strong soil mixed with blocks of stone, and below that a foot of drainage. There they grow not more than from 4 to 5 feet high, making from six to ten flowers on a stalk; but up to this time—namely, the end of August, at which the flowering of many is past, they are quite healthy. Still, it must be confessed that the English climate, with its summer storms of wind and rain, is not quite suited for a flower so liable to be damaged by weather as that of *L. auratum*." It will thus be seen that it was only after repeated trials in all parts of the

garden that Mr. Wolley Dod attained success. Bulbs are certainly cheap enough to induce everyone to follow his advice and endeavour to find the most suitable situation to insure success. Mr. Luckhurst's idea of associating them with shrubs is a highly commendable one, affording as they do a most pleasing contrast. We have fine and well-established clumps of *L. longiflorum*, *L. Thunbergianum*, *L. lancifolium rubrum*, *L. bulbiferum*, *L. tigrinum*, and *L. candidum* growing in beds and borders. I am glad to see Mr. Luckhurst grows a number of the most effective of autumnal-blooming plants, *Scbizostylis coccinea*, also the very handsome and charmingly flowered *Tygridias*. The latter succeed remarkably well us. A top-dressing of rich decomposed dung will assist both growth and flower wonderfully.—T. W. SANDERS.

STORED-UP SAP.

IF any other persons who have taken part in this discussion will say that they endorse the statements in "Non-Believer's" letter on page 27, I shall have more to say on the points therein noticed; but I refuse to take up valuable space with merely personal matters, or in re-arguing points which are already decided in my favour. I have evidence from several quarters that the discussion, so far as it has gone, has been valuable and instructive to many readers; and, inasmuch as it has caused me to look up some authorities with greater zest than usual, it has in an indirect manner been useful to myself, and I have had the satisfaction of finding support in quarters where I did not expect it. For this, readers of the Journal, including myself, are indebted to "Non-Believer." I am still willing to argue any points for a similar purpose, but when we cease to be instructive either to ourselves or others let us stop and give up the space to more important matters.

In the last two lines of "Non-Believer's" letter already referred to there is a sentence which contains matter for legitimate argument, and I will willingly wield my pen in defence of my views. But first let me ask, Why does your correspondent want to go back to "experienced gardeners" for support on any theoretical matter? In one of his previous letters he expressed a wish to have the points raised decided by the "authorities at Kew or elsewhere." Did not the revelations of the microscope satisfy him as far as they went, or was he disappointed? If he is a gardener they ought to have taught him a valuable lesson, as they did myself. It is generally acknowledged that "experienced gardeners" as a class do not go very deeply into these matters, and although I have plodded away in a rough sort of manner and found out some little wrinkles for myself, there is very much remaining of even vital importance which I should like to see cleared up by a series of investigations by competent authorities, and this brings me to the point I have to notice.

"Non-Believer" says that my idea that "the Vine has an economy peculiar to itself" is groundless. It may be; but if so, will he kindly answer the following questions? First, Is it common for plants and cuttings from such plants to root as freely from the upper as from the lower end, and thus reverse the order of their growth? Will the Gooseberry, Rose, or Geranium inserted in the ground bottom upwards commence freely making a head where in the natural order of things its roots ought to be produced? Isolated instances of plants existing after being blown over and having their tops partly buried are not to the point. Can they be made to grow freely the reverse way with any degree of certainty? The Vine can, and it appears to be almost immaterial to it which end it grows from, whether as a layer, a cutting, or a graft.

Second, What plant besides the Vine will subsist almost equally on the bare rock or without soil (see page 27, in the notice of Wilton House), and in the richest nitrogenous material—*e.g.*, the dead body of a horse? It may be new to some of the younger readers of this Journal to be told that not very long ago carrion used to be considered essential to the production of first-class Grapes, and that borders are probably still in existence where horses and cows were buried. Even Dr. Lindley held that a soil could not be too rich for either Roses or Vines. We now know that the worthy doctor, as well as many of his contemporaries, were slightly in error in this respect, and that over-manuring has led to many failures.

Third, What plant besides the Vine makes leaf-growth before it makes root-growth? There may be some, but I have not yet found any to do so habitually. With most of the cultivated fruits root-growth commences first. The Plum stock, whether it is used for bearing a Plum or a Peach, commences root-action under natural or good artificial conditions some time before there is any sign of the leaf unfolding.

Fourth, What plant besides the Vine may be found in fairly good condition both in soil which is as hard as a turnpike road and that which is as loose as a cinder heap? Not long ago it was considered the correct thing to make Vine borders up loosely and forbid any trampling on them, and who can deny that very excellent Grapes were produced? Now we go to the opposite extreme and make them very firm, and yet equally good fruit is grown.

Fifth, What plant is so able as the Vine to take care of itself under very trying conditions? If the soil it is planted in does not suit it, although prepared in a very elaborate manner and tended with the greatest possible care, it will ramble till it finds something suitable, although it has to pass through what we should consider very unsuitable

material to reach it, such as a bed of clay or a gravel walk, and even bricks and mortar in the form of solid masonry will not long arrest its progress. I have lately found an entire vegetable plot some 40 feet from a Vine border almost filled with Vine roots in better condition than they were in the well-prepared border. The reason probably is that the border, which is in a warm spot and slopes to the south, has at times suffered from an insufficient supply of water; the roots therefore travelled in search of the needful moisture, and although they must have been frequently cut off with the spade, the annual reproductions were sufficient to keep the Vines in a fairly good state of health, and Madresfield Court especially did exceptionally well. I wonder, too, what plant besides the Vine could exist with the scrapings and dressings it has long been subjected to.

Sixth, What fruit besides the Grape, having no natural keeping properties, after being severed from the plant will retain all its fresh appearance for months by merely inserting its stem in water? There is another point here, too, which is interesting. So long as the stem with the fruit on it touches the water the latter remains sweet, at least I have proved it to do so for five months without charcoal or anything added; but immediately the stem ceases to touch the water the latter rapidly becomes putrid, and this I think points to a certain amount of circulation (not mere absorption) between the water and some of the constituents of the fruit. We know also that the Grapes if left on the Vine and kept from decaying till growth commences the following year will partially regain their plumpness, and in some cases under experiment they have even absorbed sufficient to burst their skins. I cannot remember any other fruit which will do this.—WM. TAYLOR.

AN ESTIMATE OF VEGETABLES.

SEED catalogues are now being distributed; many of them are works of art, welcome to all, and prove a source of pleasure to recipients, yet to some they are bewildering. They are pleasing when the cultural notes they contain are simple yet practical, and the numerous woodcuts truthful, while they bewilder the inexperienced, especially owing to the great variety to select from, the whole being apparently of nearly equal merit. This, to a certain extent, is old ground, but those not requiring information in the matter must remember that there are many who do. I shall endeavour to give an impartial opinion upon the merits of all, adding a few notes to each section.

ASPARAGUS.—This season we were enabled to decide upon the qualities of the Argenteuil varieties of Asparagus, and find that the Early Giant Purple is certainly a few days earlier than any other we have, and the Late Giant Purple is also very good, though a doubtful improvement on a good selection of the old Giant or Battersca, and certainly not so large as Connoyer's Colossal. Any variety will grow to a good size if allowed plenty of room, and consequently all the old much-crowded beds should be gradually broken up and the crowns forced. If a new bed is formed each season one of the oldest may be lifted for forcing. Home-raised plants are preferable to any bought from a distance, which are almost certain to have their roots nearly dried up instead of bristling with lively rootlets at planting time, therefore thinly sow a few lines annually, one ounce of seed being ample for a small garden.

BEEF has grown much too strongly this season, especially where sown by the middle of April. We usually sow an ounce of the Egyptian or Turnip-rooted about that time, and the roots obtained are very acceptable for the earliest supply. The first week in May is quite soon enough in most localities for sowing that best of all Beets, Dell's Crimson, or any of its synonyms, such as Carter's Perfection, Suttons' Improved Dark Red, and Veitch's Improved Black, while Nutting's and the strong-growing Pragnell's Exhibition are best sown about the middle of May. The latter is rather too coarse, but from our late-sown bed we were able to pick a considerable number of clean handsome roots.

KIDNEY BEANS.—I still prefer Osborn's Forcing for pot culture, and also for the earliest crops on sheltered borders. Cooling's Ne Plus Ultra will not supplant it for either work. It is not compact enough, nor is it particularly prolific. I should much like to see a specimen of it similar to that which is figured in all the catalogues. For succession and main crop the preference is still given to Canadian Wonder and Negro Mammoth Long-podded. In some seasons the former proves the most profitable, and yields the greater number of exhibition pods. Such was the case during 1881 and 1883, while in 1882 the latter was the favourite. That is why both are grown, and we are then certain to have one of them very good. Carter's Longsword, a white-seeded variety, is a profitable variety, especially if grown for the seeds, these being harvested and sent to the kitchen when Haricot Beans are required. The White Dutch Runner Bean is also preferred to the White Haricot, and is grown especially for the seed. Scarlet Champion and Suttons' Giant White Runner both yield abundance of good pods, and are the best for exhibition purposes.

BROAD BEANS.—The Early Longpod is still the most profitable early Broad Bean. Seville Longpod produces much longer and more handsome pods, and is early, but with me is shy-bearing unless planted out from pots. The finest of all is Carter's Leviathan, this variety under fairly good cultivation producing abundance of long straight pods, which attain a length of 12 to 14 inches, and for exhibition purposes are unequalled. For the main and late crops Broad Windsor Improved and Green Windsor are preferred.

BORECOLE OR KALE is not much grown here. For the earliest supplies I recommend any seedsman's Dwarf Green Curled, while for spring supplies the Asparagus, or Buda as it is also termed, is invaluable. Both the purple and green forms are perfectly hardy, and the late greens yield most abundantly and are delicious. We have had it good in June, and during the spring of 1883 was the only available green stuff besides Brussels Sprouts.

BROCCOLI.—This is always an important vegetable, and not a little depends upon the choice of varieties. Veitch's Self-protecting Autumn has been particularly good this season, whereas last year it was a failure. A few autumn-sown plants a friend gave me formed wonderfully fine heads during September, and were hardly distinguishable from the Autumn Giant Cauliflower. The plants obtained from the early spring sowings hearted-in during November, and were not quite finished when the earliest batch of the invaluable Snow's Superb White were being cut late in this month. The weather not being very severe we shall continue to cut this hardy sort till February, when Veitch's Spring White should be ready for use. The latter is a good variety, one of the best in fact, and to succeed it I have Osborn's Winter White. This dwarf and distinct variety never hearts here until early or late in March, according to the weather experienced, early sowings not resulting in such early crops as the description has led me to expect. We invariably plant a large breadth of Leamington, and unless a very severe frost damages the rather long stems we are certain to obtain a fine lot of heads during March, April, and sometimes into May, a glut rarely occurring. Cooling's Matchless is a fine April variety, so also are Suttons' Perfection and Carter's Mammoth Spring White. Of late sorts Miller's Dwarf, from the fact of its being really dwarf, is also one of the hardiest, and that is why we grow it. It does not produce very good heads. Model is undoubtedly a model late Broccoli, and is perhaps unequalled in its colour and quality, so well is it protected. Veitch's Wilcove Improved is also hardy and good, and the same may be said of Cattell's Eclipse. Suttons' Late Queen is very fine during May, and sometimes in the early part of June, and is one of the hardiest. Ledsham's Latest of All is dwarf and promising in appearance, and if all accounts are true is a very desirable addition to our very latest section. If I could procure the true Early White Cape this would be grown for storing in frames for use during the early winter months, but we get Walcheren substituted for it, and this variety invariably hearts-in when we have plenty of late Cauliflowers. Penzance Early White is a rank-growing useless variety, only a moderate frost cutting it down. Several other catalogued sorts are very good, but I give the preference to the commended varieties above.

BRUSSELS SPROUTS.—Veitch's and Suttons' Exhibition and the Aigburth have all done remarkably well here, but the imported form has not been nearly so profitable as usual. The former were at one time supposed to be too coarse, but no complaint has reached me this season, and now, were I to confine myself to one variety, it would be the Aigburth.

CABBAGES.—Ellam's Dwarf Spring and Reading All Heart have been the best this year, and I much like a small unnamed variety received for trial from Messrs. Sutton, but as this firm does not favour us with the names of their novelties they ought perhaps to be omitted. London or Rosette is still about the best of the Coleworts. Chou de Burghley grew to a great size, much too large in fact, formed large and close conical-shaped heads, and when thoroughly cooked were of very good quality. It, however, does not get beyond the servant's hall, and at that rate does not pay for the room occupied. I have seen plenty of neater heads or mongrels among a breadth of early Broccoli growing near the town of Frome.

CARROTS.—There are not many varieties of these to choose from, and of these few I rely almost exclusively upon the Nantes Horn. It is the best for forcing in frames, and the best for early, main, and late crops in the open ground, all that is necessary being to sow the seeds at intervals from March till late in June, the principal breadth being sown early in the last month. It is preferred to all others in the kitchen, and by sowing frequently we have nearly always fit for drawing an abundance of very tender and sweet young roots. I usually grow a few Long Surrey for keeping in case of failure near the end of the season.

CAULIFLOWERS.—The best of these for growing in frames and

handlights is the Extra Early Forcing, this, I believe, being very similar to Dean's Snowball. It is particularly good for sowing in heat in spring, in the case of plants from autumn-sown seed being scarce. Early London and Dwarf Erfurt Mammoth, the latter being preferred by me, are both good for early crops, and to succeed these Veitch's Pearl is recommended. We found this novelty decidedly good for the main crop, as it produced good heads till long after the autumn and earliest spring-sown plants of Veitch's Autumn Giant were hearting-in. The latter can, as a rule, be had very good until December if sown late in May. Eclipse, in the way of Autumn Giant, is much earlier, and is invaluable in gardens where there are no facilities for raising an early batch of plants of the latter. Walcheren Cauliflower I do not believe in.

CELERY.—Our earliest Celery is secured with the aid of a superior form of the Dwarf White Incomparable, selected by Mr. D. Thomson, Drumlanrig, but as this cannot be bought I should recommend Sandringham Dwarf White or a new variety of Suttons' in lieu of it. Williams' Matchless Red grows to a good size, is of excellent quality, and well adapted for exhibition purposes. The true Leicester Red and Major Clarke's Solid Red are of about equal merit, and both are remarkably solid, crisp, and good. Carter's Incomparable Crimson is also very good, and is perhaps the most hardy of all.

ENDIVE.—Moss-curl is excellent for the earliest crops, this to be followed with either Green-curl or Picpus Green-curl, while for the latest crops the Improved Round-leaved Batavian is invaluable.

LETTUCES.—The very quick-growing Early Paris Market is the best for frames and sheltered borders. Tom Thumb for the autumn, and Hardy Hammersmith to stand the winter, are the only other Cabbage varieties we grow. With regard to Cos varieties, I am completely converted to Mr. Taylor's opinion that the Black-seeded Brown Cos is by far the best variety for nearly all seasons. If greener sorts are preferred, and we generally sow a row at the same time as we do the brown sort, I should recommend one of the many selections of Paris White Cos. Hick's Hardy Green is one of the hardiest sorts we have.

LEEKs.—I am afraid our seed of the new Lyon Leek was "cooked," at any rate none of it germinated, although treated exactly the same as the Ayton Castle Giant and Musselburgh. The latter is not so large as the Ayton Castle, but either are good enough for ordinary purposes. The Carentan is much too coarse-grained, and will not long remain in cultivation.

ONIONS.—I find the White Neapolitan Tripoli early and good, this being followed by the Giant White Madeira, with Giant Rocca for keeping. For spring sowing I like Banbury Improved, this being large and handsome. If larger than this is required Walker's Exhibition should be grown. Besides the foregoing I much like Giant Zittau, believing it to be one of the most profitable sorts catalogued. It is very heavy and keeps well. Brown Globe completes the list.

Most seedsmen now possess an extra good strain of Curled Parsley, and besides this the Fern-leaved variety may well be grown. I prefer the Student Parsnip, and often wonder why so few Parsnips are grown and eaten. Radishes of the Extra Early Dwarf Top type, French Breakfast, and Wood's Frame are good for forcing, and there are several new sorts also good. Wood's is also the best for a sheltered border, and the Long Red is grown to succeed this, and also for late work. The Red and White Turnip varieties are the best for summer sowings. Of Rhubarbs I give the preference to Johnson's St. Martin's for forcing, but it seldom comes true from seed. Royal Albert is also early and good, and Myatt's Victoria grows to a great size.

SAVOYS.—Tom Thumb and Little Pixie Savoys are both excellent, neat-growing, and early. Early Ulm forms a good succession. To follow this we have Dwarf Green-curl, and the latest crops are of Drumhead.

SEAKALE AND ARTICHOKEs.—Seakale is easily raised from seed, but can be grown to a much larger size in one season from small pieces of roots. Globe Artichokes may also be raised from seed, but half of the seedlings are of no value when grown, this being most marked with the Purple Globe varieties.

SPINACH.—The Round or Summer variety is good for either early or late sowings, being quite as hardy as the Winter or Prickly-seeded. A few plants of New Zealand Spinach reared in heat and planted on a sunny border will during the summer yield a great number of shoots at a time when the other sort completely fails.

TOMATOES.—The Dwarf Orangefield Tomato is still one of the best, especially for pot work; and the Large Red, or a good selection of it, such as Earley's Defiance, crops still more heavily both under glass and in the open. Phillip's Perfection is one of the handsomest varieties I am acquainted with, and the quality, too, is first-class. Dedham Favourite is handsome and good, and for all purposes Trentham Early Fillbasket is to be recommended.

TURNIPS.—The Early Munich is much the earliest variety we

have, but that is its only recommendation, as it is very inferior in quality. To succeed this a good selection of Snowball, such as Jersey Lily, may well be grown, while for autumn and winter Veitch's Red Globe is much the best. The hardiest is the Chirk Castle Black Stone.

VEGETABLE MARROWS.—We only grow the Long White. The Custard Marrow is much liked by some, and Muir's Prolific Hybrid is also highly spoken of; it was the raiser's fault that I am unable to speak concerning its merits. As I have already written at considerable length, remarks I wish to make concerning a considerable number of Peas and Potatoes must be deferred.—W. IGGULDEN, Marston.

PROFESSIONAL GARDENERS' FRIENDLY BENEFIT SOCIETY.

ALTHOUGH this Society was established in Leeds and has been successfully managed there by a Committee of gardeners for several years, it is very far from being of a local character. All *bona fide* gardeners are eligible for membership, and a considerable number reside in different parts of the country. It is customary to have an anniversary dinner yearly, at which the Mayor of the town with other influential gentlemen attend, as the Society is regarded as eminently worthy of their countenance and support. The seventeenth meeting of the nature indicated was held on the 11th inst., Henry Oxley, Esq., presiding, supported by John Barran, Esq., M.P., Councillor Loe, and G. W. Morrison, Esq. (Town Clerk). Letters of apology were read from the Mayor, W. L. Jackson, Esq., M.P., and Herbert J. Gladstone, Esq., M.P. There was a very large attendance, including a number of visitors, the representatives of provincial nursery firms, and others, the spacious room being crowded. After the usual loyal toasts the following report of the Society was read by Mr. W. Sunley, the Secretary:—

REPORT OF THE PROFESSIONAL GARDENERS' FRIENDLY BENEFIT SOCIETY

In presenting the seventeenth annual report, your Committee beg to direct attention to the annexed balance sheet, which shows cause for satisfaction.

	£	s.	d.
The Society's income for the past year has been	182	16	10
Its expenditure for the same period has been	156	13	2½
Which leaves a saving for the past year of	26	3	7½
This amount, added to the savings of the sixteen previous years of	£649	2	10
Makes the total amount now placed to the Society's credit of	£675	6	5½

Representing the value to each financial member of £6 2s. 9½d.

Your Committee beg gratefully to acknowledge the very liberal support accorded to the Society by its honorary members, and cordially welcome the five additional gentlemen who have been enrolled during the past year.

The Society now numbers seventeen honorary and 110 ordinary members.

Henry Oxley, Esq., very generously offered to give £5 to further encourage members contributing and reading essays at the monthly meetings. After careful consideration it was thought advisable to apportion this amount into three prizes. Eight essays have been contributed during the year, but only three members consented to enter for competition. These three essays were duly forwarded to the Editors of the *Journal of Horticulture*, who very kindly consented to adjudicate the order of merit. The first prize of £2 10s. was awarded to Mr. George Winterburn, gardener to Lomas Joy, Esq., Weetwood Lane. Subject, "Furnishing the Conservatory."

The second prize of £1 10s. was awarded to Mr. James Inman, Chapel Allerton. Subject, "Cultivation of the Vine."

The third prize of £1 was awarded to Mr. William Jackson, gardener to Henry Milligan, Esq., Benton Park, Rawdon. Subject, "Cultivation of *Eucharis amazonica*."

As these essays are the means of exciting much discussion and emulation, and thereby diffusing much useful knowledge, your Committee most earnestly hope members will continue to render their support in this very important matter. The best thanks of the Society are due to Mr. Oxley for his generosity, and to the Editors of the *Journal of Horticulture*, who have so kindly given their valuable services, also to the several members who contributed the essays.

Your Committee will always endeavour to promote the welfare of the Society, and continue to rely on the kindly forbearance and support of the members generally.

Bacchus Hill, Moor-Allerton,
January 1st, 1884.

Signed on behalf of the Committee,
WILLIAM SUNLEY, Secretary.

The distribution of the above-mentioned prizes was a feature of the meeting, and the Chairman in an excellent and practical address pointed out the great advantages of the practice of preparing such essays both to the writers of them and those to whom they were read and who shared in the discussions thereon, promising also to give a similar amount in prizes to be competed for another year. Mr. Barran in responding to the toast of the borough members said he felt happy in being present among so many of Nature's gentlemen who were not only cultivating plants, but the taste of the people also; and every step taken in gardening tended to elevate and refine that taste. Much fault was found with Parliament as to the way in which its money was spent, but in no department of expenditure had there being more satisfaction than in that which had reference to horticulture. All that had been done at Kew and Battersea Park had been received on the part of the public with the utmost satisfaction. He should be glad to see some of the northern towns, although they had to contend with difficulties of climate, emulating Parliament by doing something in the way of providing flower gardens. Next to the expenditure on education, the cultivation of plants and flowers would be a very great boon to the people, and would be exceedingly well-spent money. Taking it on the whole, there were very few investments which paid better than this, or which tended more to improve the moral tone of the people. Taking a still more narrow view, in everyday life people

ought to be grateful for what was provided by gardeners. There was a good deal of enjoyment to be got out of plants, and whether in or out of doors our happiness was very much increased by the labours of those who cultivated flowers. He hoped the study of horticulture would be developed, and that the people would be induced to contribute rather more freely than they had done towards the attainment of that end. It was of the utmost importance that they should maintain the stability of the Society; and it was to be hoped its usefulness would be extended in the direction of essays on subjects which came within their everyday life.

Some particulars of the Society will be given, but in the meantime its condition and working, as succinctly embodied in a speech by Mr. Sunley, will indicate its character:—

"In responding to the success of the Society in the absence of Mr. Featherstone I will go back as far as 1880. That year the income amounted to £116, and £79 was paid for sickness and death. In 1881 the income was £107; paid for sickness £18; the most successful year the Society experienced. In 1882 the income was £116; paid for sickness and death, £104, that being the heaviest year for sickness and other causes we have had. In 1883 the income was close upon £183, and payments £92. That gives a total saved during the four years of £229 to meet other light expenses. When a member is unable to follow his employment through sickness he receives £13 for the first twenty-six weeks, and 5s. per week as long as he is ill. At the death of a member his widow receives £10. At the death of a wife the member receives £7. At the end of seventeen years there is a saving of £675, and the payments for all these advantages only amount to 13s. each member yearly, except when a death takes place a levy is made of 1s. each for a member, and 6d. for a member's wife."

The meeting was a most enjoyable one—the best the Society has had, and the prize essays will in due time be published in our columns.

CACTACEOUS PLANTS.

GROTESQUENESS of form or habit is rarely found in combination with floral beauty in the vegetable world, yet no family affords more remarkable examples of this union of widely divergent qualities than the great and peculiar Cactus order. In many large groups of plants we find numbers possessing handsome foliage, but having only insignificant flowers, and in many others also when the flowers are more than usually attractive the foliage appears chiefly to serve the purpose of a foil to their rich or bright colours, having in itself nothing of a specially striking nature. There seems to be something of Nature's economy in thus developing one particular quality at the expense of others—a concentration of strength, which probably has a deeper meaning than we can perceive, for it is observable in the animal kingdom as well as amongst plants. The Cactus family is, however, an extraordinary exception, for, whether flowering or not, the majority of the plants constituting it are distinguished by most striking characters. They do not possess beautifully coloured or elegantly formed foliage to recommend them; on the contrary, true leaves are absent from nearly all, but in contrast to some of the most gorgeous flowers produced by plants, we see unwieldy masses of vegetable matter, spherical, cylindrical, or angular, armed with stout and formidable spines, and resembling what we might almost imagine to be the relics of a vegetation belonging to a period long prior to the development of the plant life familiar to us in the present age. Such would be the first impression; but when the brilliantly coloured rose, crimson, purple, or yellow blooms were seen the observer would be led to the conclusion that while the plant was advancing to so high a degree of floral beauty, one portion of its constitution must have been strangely stunted and altered by some external long-continued forces. There is an inconsistency of characters that must impress the least observant, and imparts an interest to the plants which increases with the knowledge we gain respecting them, for they are surrounded as it were by a degree of mystery that always adds a charm to Nature.

Cactaceous plants have therefore much to recommend them to lovers of the curious and the beautiful, but the majority also possess another very valuable character—*i.e.*, they are easily grown, so easily in fact that the cottager who can only devote a small space to them in his window may, and often does, grow many of them as successfully as the greatest magnate in Europe with all the most elaborate horticultural appliances at his command. In the dry and heated atmosphere of a room which is so trying to most plants they are perfectly at home, and their demands upon the attention of their host are so slight they may be left for weeks, nay months, without the smallest supply of water. It is not surprising, therefore, that many of the Cacti are favourites with dwellers in towns, and many a toiler has had his heart lightened by a sight of the lovely flowers produced by his window "Cactus," or has felt the pleasure of exhibiting his vegetable curiosities to his friends. Amateurs, too, in many other grades of life have found in the cultivation of these plants the satisfaction which is derived from the constant study of the wonderful phases of plant-existence; and though it can never be expected that they will rise to a popularity approaching that of the Rose, yet there is a steadily increasing demand for them, and several nurserymen now make a speciality of them. Considerable stimulus has no doubt been given to the culture of Cactaceous plants by the efforts of J. T. Peacock, Esq., Sudbury House, Hammersmith, who, with the aid of his former gardener, Mr. Croucher, formed the largest private collection in this

country, and this together with the wonderful collection at Kew has rendered the best of such plants familiar to Londoners. A large trade too, sprung up a short time ago in "miniature Cacti," and this by bringing a number of forms within the reach of most people at moderate prices has still further assisted in popularising an interesting class of plants. The claims of the Cacti to general notice having been briefly reviewed in the foregoing notes, a slight survey of the family may be now undertaken, commencing with the

STRUCTURE.

The most prominent general character of the plants comprised in the natural order Cactaceæ is the unusually large development of cellular tissue, to which circumstance they in common with some others of different families owe the popular and wide designation of "succulent plants." The stem is, with few exceptions, leafless, and varies in form

Fig. 6.—MEXICAN CACTI.

from the globular *Melocactus* to the columnar *Cereus*, being generally unbranched, except in the *Rhipsalis*, *Opuntias*, and slender-growing *Cereus*. The surface is either marked with angular ridges from base to summit, upon which are arranged with great regularity a series of clusters of spines varying in size, colour, and number, or, as in the *Mammillarias*, the surface is broken into a number of small rounded projections or *mammillæ*, each crowned with a cluster of spines. These spines in several of the genera furnish useful characters in distinguishing the species, size, colour, and number, being found to be constant in the majority of cases. They are exceedingly numerous, and specimens of moderate size of *Cereus senilis* have been found to have from 50,000 to 70,000. In size, too, the Cacti have a wide range of variation, from some of the diminutive *Mammillarias* a few inches high to the gigantic *Cereus peruvianus* which is found in its native habitat upwards of 50 feet high, and the huge *Echinocactus Visnaga*, single specimens of which have been introduced to this country weighing as much as a ton. These plants contain comparatively little woody tissue except when they are very much advanced in age, the cellular tissue being very largely developed in the

majority of the typical forms, the cells being large and mostly filled with a clear water-like fluid, but in others with milky mucilaginous or slightly acrid juices. There is also usually a quantity of crystals of oxalate of lime, which are readily seen if a stem is cut after being dried. Having no leaves the function of respiration must be performed by the stem; but as this has to serve as a reservoir of nutriment generally exposed to a burning tropical heat, it is obviously of importance that the evaporation

very frequently coloured alike, and only distinguishable with great difficulty. The colours most abundant are shades of rose, crimson, purple, and yellow, some being white and others greenish. Many flowers possess a powerful and most pleasing fragrance, but they are usually of extremely short duration, some lasting but a few hours during the evening or night. The fruit is of a fleshy substance, and in the case of several species, such as *Cereus speciosissimus* and *Opuntia vulgaris*, it is

FIG. 7.—THE SUCCULENT HOUSE AT KEW.

from the surface should be reduced to a minimum. As a means to this end we find that the stomata or breathing pores, which are so abundant on the leaves of most plants inhabiting temperate climates, are in the Cacti comparatively few. To this, together with a peculiar structure of the walls of the cells forming the superficial layer, is due the remarkable heat and drought-enduring character that enables it to live and thrive where most other vegetation would perish.

The flowers differ much in size and colour, but they mostly agree in the large number of sepals, petals, and stamens, both the former

edible, and when well ripened of a very agreeable flavour, somewhat resembling that possessed by some fruits of the Gooseberry family, to which the Cacti are distantly related.

DISTRIBUTION.

North and South America are the principal homes of Cactaceous plants, the greatest strength of the order being concentrated in Mexico, which contains nearly three-fourths of the entire number known. Brazil, Peru, Chili, Guiana, Colombia, and some other districts in South America also

contain representatives, but in relatively small numbers. In Mexico the vegetation assumes an extraordinary appearance owing to the preponderance of the Cerei and other members of the family, where in the several hot, dry, rocky, regions which characterise this portion of the American continent, the Cacti flourish together with Agaves, Yuccas, Dasylirions, Beancarnes, Echeverias, and similar plants of the Xerophilons, or heat and drought-loving type. The woodcut (fig. 6) will convey some idea of the aspect of the vegetation in many parts of Mexico; but one of the most remarkable representations of this scenery is a plate in Julius Fröbel's "Travels in Central America and Mexico," portraying the lower part of the valley of Santa Cruz, in which are shown over fifty "Saguaro trees," as the *Cereus peruvianus* is termed, some very strangely branched near the summit, and attaining the height of from 30 to 50 feet. In the Rocky Mountains some members of the family are found at great elevations, several having been observed by Mr. E. G. Loder as high as 10,000 feet. These being in a low temperature are practically hardy in this country, and form a group of additional interest to the cultivator.

HISTORY.

The Cactaceæ, or Cactææ as this family is termed by some writers, derives its name from the word *Cactus*, under which generic title Linnaeus grouped all the forms that were known in his time, and the name is still popularly applied to plants possessing the general characters of the order. Botanically it is now obsolete, and the species are arranged under other genera, such as *Cercus*, *Echinocactus*, *Opuntia*, &c. The title "Cactus," or "Cactos," was applied by Theophrastus to some kind of spiny plant peculiar to Sicily, which, there appears good reason for supposing, was really *Cynara Scolymus*, the Artichoke, and therefore it was erroneously adopted for a class of plants widely separated from the *Compositæ*. Dioscorides, Athenæus, and Pliny mention this *Cactus*, but apparently referring to the same plant. A plant is also mentioned by Pliny under the name of *Opuntia*, which has been by some supposed to be *Opuntia vulgaris*. The passage runs thus—"About the city of Opus this an herbe called *Opuntia* which men delight to eat; this admirable gift the leafe hath, that if it be laid on the ground it will take root and there is no other way to plant the herbe and maintain its kind."—(*Holland's Pliny*). There is, however, much uncertainty about this, although the *Opuntia* has been long naturalised in Europe. Coming to our own country the earliest record of any cultivated members of the family occurs in Gerard's "Catalogue of Plants" (1596), in which he mentions the *Ficus indica* (*Opuntia vulgaris*) as having been brought from Zante by his servant, William Marshall. In his "Historie of Plantes" (1633) a good figure is given of it, also in Parkinson's "Garden of Pleasant Flowers" (1629) and "Theater of Plantes" (1640), the latter mentioning two forms, major and minor, the Greater and Lesser "Indian Figge Trees." One of these was included in the collection at the Oxford Botanic Garden, for in the catalogue dated 1658 is mentioned the *Ficus indica spinosa minor* of Parkinson. In the succeeding fifty years several species were introduced, chiefly through the Earl of Portland, and to the Royal Gardens, Hampton Court; so that in 1716, when Richard Bradley published his interesting little work on succulent plants, he was able to describe and illustrate five forms, chiefly *Cerei* and *Opuntias*. In the same author's "Philosophical Account of the Works of Nature" (1739) good figures are also given of a *Cereus*, *Melocactus*, and *Opuntia*, with some description and reference to his previous work. During the eighteenth century Mr. Phillip Miller of the Chelsea Gardens brought several Cacti into notice, at least eight being credited to him and described in his "Gardeners' Dictionary" in addition to those already known. By the end of this century, as we find from Wildenow's edition of Linnaeus' "Species Plantarum" (1796), twenty-nine species were in cultivation or known to botanists, and all were arranged under the head "Cactus," the specific names being mostly the same as those adopted now. Martyn's edition of Miller's "Gardeners' Dictionary" (1807) enumerates twenty species as follows: *Cactus*, *Mammillaria*, *Melocactus*, *Pitajaya*, *heptagonus*, *tetragonus*, *hexagonus*, *pentagonus*, *repandus*, *lanuginosus*, *peruvianus*, *Royeni*, *grandiflorus*, *flagelliformis*, *parasiticus*, *pendulus*, *triangularis*, *moniliformis*, *Opuntia*, *Ficus indica*, *Tuna*, *cochinellifer*, *curassavica*, *Phyllanthus*, *spinosissimus*, *Percskia*, and *portulacæfolius*. From Aiton's "Hortus Kewensis" (1811) we learn that twenty-four of these were cultivated there, while when Haworth's "Synopsis Succulentarum" was issued in 1819, about forty-five species or varieties were known.

The increase from this time was rapid, for Sweet's "Hortus Britannicus," 1826, enumerates ninety-four as in cultivation, while Decandolle's "Prodromus," published two years after, describes or mentions 183 under seven genera. The number of botanical travellers in America during the following twenty years added greatly to the knowledge of these plants, and by 1840 there were nearly 400 forms in cultivation (*Paxton's "Botanical Dictionary"*), which by 1850, when M. Labouret issued his elaborate "Monographie des Cactées," had increased to 670. Since then many others have been discovered and introduced, and a few years ago Mr. Jackson of Kew estimated the number of species at about 950, though at the present time they probably exceed 1000. Comparatively few large collections of Cacti have been formed, and in recent years there has been none to equal those at Sudbury House, Hammer-smith, and in the Royal Gardens, Kew. In the latter establishment the handsome house devoted to succulent plants has long been one of the chief attractions to visitors, who can there inspect a conspectus of one of the most extraordinary types of vegetation upon the globe. A view of a portion of this house is given in fig. 7, showing the *Cerei*, *Melocacti*, and other members of the family, nearly 300 species and varieties being included in the collection.—LEWIS CASTLE.

(To be continued.)

THE NATIONAL CHRYSANTHEMUM SOCIETY will hold their annual general meeting at the Old Four Swans, 84, Bishopsgate Street Without, at seven o'clock precisely, on Thursday evening next, the 17th inst. The President of the Society, E. Sanderson, Esq., will take the chair. The business will include reading the minutes of the last meeting, the report and balance sheet of past year, election of officers and Committee for 1884, and to consider suggestions that may assist the Committee in compilation of the schedule for 1884.

— THOUGH not a very common plant *LONICERA STANDISHI* is perfectly hardy in our climate, and merits a place in every garden where room can be spared in company with *Jasminum nudiflorum* and the well-known *Chimonanthus fragrans* and *grandiflora*. Flowering in front of No. 1 museum at Kew, passers-by get a good share of the delicious fragrance emitted by the small white flowers. Unlike the *Jasmine* it has a good clothing of dark green leaves, which is a character greatly in its favour.

— "A. L. G.," writing concerning FRAGRANT ROSES, remarks:—"If anyone fond of highly scented H.P. Roses does not possess *Ulrich Brunner* I strongly advise them to get it. It is a very bright, clear, cherry-rose, with enormous flowers of exquisite scent, a really good variety; and I may mention as a very fragrant Rose, though not a H. P., that grand climber *Cheshunt Hybrid*. I venture to call Mr. Simons' attention to a slight mistake in his list (page 4). *Marie Van Houtte* is a Tea Rose, at least the one I possess is." Perhaps it was a misprint for *Louis Van Houtte*.

— THE beautiful stove plant *TILLANDSIA LINDENI* is referred to approvingly on page 24 as bearing light blue flowers. A small plant has for some weeks been flowering in Mr. Major's multum in parvo garden at Cromwell House, Croydon, the colour of the flowers being of the deepest blue imaginable. This is no doubt the true variety, *T. L. vera*, than which few if any blue flowers are richer. It is strikingly handsome, the white centre being very clear, and appearing to render the dark glowing petals additionally attractive.

— A WELL-ATTENDED meeting of the LIVERPOOL HORTICULTURAL ASSOCIATION was held on the 12th inst. in the Free Public Library, William Brown Street, under the presidency of Mr. Thomas White. The subject under notice was an essay on "Forcing Roses" by Mr. W. Bardney, Norris Green, who treated the matter in his usual practical manner. At the conclusion of a long and interesting discussion a hearty vote of thanks was unanimously accorded Mr. Bardney for his excellent paper. Mr. Mark Wood, gardener to Col. Wilson, received a vote of thanks for a box of very fine Tomatoes, the variety being *Trophy*. The fruits were of fine colour and large, fully equal to many of the handsome examples we are accustomed to see at summer exhibitions. The usual compliment to the Chairman brought to a close a most interesting and instructive gathering.

— "B." considers *IMANTOPHYLLUM MINIATUM* one of the best plants for forcing into bloom about Christmas and onward that can be had. It is free-flowering, and merely requires to be grown throughout the winter months in a growing temperature to insure it flowering annually at the dull season. In summer it is best grown in a greenhouse. Plants which flower now do so again about June. The flowers are admirably adapted for vase-decoration. We employ loam and crushed lime rubbish as potting material, and do not stint the water.

— IN reference to CELERY CULTURE IN AMERICA a Mr. Stearns at a recent meeting of the Michigan Horticultural Society gave an account of Celery culture at Kalamazoo, where 500 acres were raised last year and five to eight tons shipped daily from each of the two express-offices. "The Celery is packed in boxes made especially for the purpose. The producers receive twenty cents a dozen bunches. The seed is sown in a bed prepared for the purpose; the plants not transplanted until they are put in the trenches. A layer of manure is spread in the bottom of the trench before the plants are set; the plants are set 6 inches apart in the row. For the early crop the seed is sown in hotbed and trans-

planted about the 1st of May. In Kalazamoo but little is stored by the producers; that which is stored is packed in pits covered with low sheds. For a few dozen one of the best ways of storing is to put in a box in the cellar on the bottom of which is a puddle of earth and water to cover the roots. Professor Tracy said marsh Celery does not keep so well as that raised on upland..”

— “M. S.” writes with regard to HELLEBORES:—“We are having enough pedigrees about these plants to last us for at least twelve months and confuse us still longer. A fine plant exhibited in the greenhouse at Kew growing in a pot, presented by Mr. Brockbank, and named *H. niger angustifolius*, Brockhurst var., is certainly handsome and well worth growing for greenhouse decoration, it having over 100 flowers open at present. Another in flower in the Heath house, and said to be the true “St. Brigid’s,” will puzzle many critical florists to distinguish it from the above, the only difference at present being to a casual observer the paucity of leaves on “St. Brigid’s” while the Brockhurst var. is well clothed, but they are otherwise alike. Both undoubtedly differ from the true *altifolius* in having very much narrower leaves and less rose blush on the petals.”

— “THE ROSARIANS’ YEAR BOOK FOR 1884” (Bemrose and Sons, 23, Old Bailey) is now issued, and contains as its frontispiece an excellent portrait of J. McIntosh, Esq., Vice-President of the National Rose Society. The articles are the following:—“The Rose Election of 1882 Compared with Experience,” by E. R. Whitwell; “Roses on their own Roots,” by J. Brown; “The Battle of the Stocks and Buds,” by D. T. Fish; “Old-fashioned Roses,” by Julius Sladden; “Roses in 1883,” by the Editor, the Rev. H. Honeywood D’Ombrain; “Roses in Cheshire,” by T. B. Hall; “Gossip on Scotch and English Rose Shows,” by Alexander Hill Gray; “Rose Election of 1883,” by Joseph Hinton; “Real Autumn-Flowering Roses,” by G. Paul; and “The Rose Weather of 1883,” by E. Mawley. All these are instructive and interesting, but they are sober, and we miss the leaven of humour which has generally characterised some of the articles.

— MR. JOSEPH MALLENDER, Hodsock Priory, Worksop, Notts, sends the following record OF THE WEATHER IN 1883. Total duration of sunshine 1330 hours, or 30 per cent. of the possible duration. There were seventy-six sunless days. Total rainfall 29.83 inches. Greatest fall in twenty-four hours on the 25th of May 1.09 inch. Rain fell on 194 days. Mean temperature 47.8°. The warmest day was the 29th of June; mean temperature 68.4°. The coldest the 10th of March; mean temperature 21.7°; mean temperature of air at 9 A.M. 48.3°; mean temperature of soil 1 foot deep 48.6°; number of nights below 32° in shade fifty, on grass 124; highest reading of barometer on the 4th of March 30.745; lowest reading the 2nd of September 28.656. The principal features have been the excessive cold in March, the dry period from the middle of February to the middle of April, the absence of any hot weather, and the scarcity of sunshine in summer, a wet September, an unusual absence of frosts during the latter part of the year, and the severe gale in December.

— THE same correspondent records THE WEATHER IN DECEMBER LAST as follows:—Total duration of sunshine in the month 27.8 hours, or 12 per cent. of possible duration, the most in one day; on the 4th and 6th 4.4 hours. There were sixteen sunless days. Total rainfall 1.17 inches. The greatest fall in twenty-four hours was on the 16th, 0.24 inch. Rain fell on nineteen days. Wind principally southerly to westerly; average velocity 14.5 miles per hour; velocity exceeded 400 miles on fourteen days. The mean temperature of the month 40.4°. Warmest day, 14th; mean temperature 51.8°. The coldest day the 6th; mean temperature 33.7°. Mean temperature of air at 9 A.M. 39.5°; mean temperature of soil 1 foot deep 40.5°; number of nights below 32° in shade two; on grass sixteen. The highest reading of barometer on 7th 30.602; lowest reading on 11th, 29.355. The month was remarkable for the high night temperature and the small number of frosts in the shade. The rainfall was less than in any of the previous eight years except 1879, when it was the same. Sunshine more than last year, but less than in 1881. The gale on the 11th did much damage. Many trees were blown down.

— WE learn from the *Herts and Essex Observer* that the eighth anniversary DINNER AND ENTERTAINMENT in connection with the sick fund attached to the Sawbridgeworth Nursery was celebrated by the

employés in a most agreeable manner on Thursday evening, the 3rd inst. The fund was originated at the instigation and through the efforts of Mr. Wm. Camp, Messrs. T. Rivers & Son’s able and obliging manager; and the firm, highly convinced as they are of the desirability of encouraging provident habits, have not only given it their hearty concurrence but a judicious modicum of material support, which has manifested itself in more ways than one, and especially on the occasion of these annual reunions. Between fifty and sixty sat down to dinner, the chair being occupied by Mr. Wm. Camp and the vice chairs by Mr. W. Tarling and Mr. J. Dedman, department foremen. A number of toasts were proposed and duly responded to, and the Chairman stated that the institution was in a flourishing condition, notwithstanding the drain upon their resources, for there had been more sickness last year, and consequently additional claims, than had been known for a long time past. But after all demands had been met, there was still an increase of the balance in the post office savings bank. The Hon. Sec. of the fund is Mr. W. Carter, whose ready services in its behalf are highly valued. An extremely pleasant entertainment of music and singing followed and concluded a most agreeable evening.

— PART 86 of Boswell’s and Sowerby’s “ENGLISH BOTANY” continues the descriptions and illustrations of the Ferns, comprising *Polystichums*, *Woodsias*, *Cystopterises*, *Athyriums*, *Scolopendriums*, *Pterises*, and *Adiantum*. The *Equisetaceæ* are also commenced, *Equisetum maximum* and *E. arvense* being very fully described. The plates continue as faithful and praiseworthy in general execution as those we have previously referred to.

— MESSRS. ELLWANGER & BARRY, Rochester, New York, thus describe two new American Roses that have been raised by them:—“The HYBRID PERPETUAL ROSE MARSHALL P. WILDER was raised by us from seed of *Général Jacqueminot*, and has flowered three seasons, giving us ample time to judge correctly of its qualities. It is of vigorous growth, with healthy foliage; flowers large, semi-globular, full, well formed; colour cherry carmine, much like a light-coloured *Marie Baumann*, or a shade deeper than *Marie Rady*, and very fragrant. In wood, foliage, and form of flower it resembles *Alfred Colomb*, but the seedling excels that famous variety in vigour, hardiness, and freedom of bloom. The past season it continued to bloom profusely long after the *Remon’ants* were out of flower. In brief, it may be described as an improved *Alfred Colomb*.”

— “THE TEA ROSE ROSALIE, OR FAIRY QUEEN, was raised by us from seed of *Marie Van Houtte*, and has been tested in our houses for some time. It is of slender yet healthy growth; foliage small, dark green; flower small, a little larger than *Paquerette*, and of a deep pink colour, about the shade of *Madame Lambard*. It is very pretty in bud, and the open flowers are of good substance, and remain perfect for a long time. It has a pleasing fragrance. One of its prominent traits is remarkable freedom of bloom, every shoot producing a flower. We consider it a distinct and charming miniature Rose, and a valuable addition to the list of varieties suitable for forcing.”

PRUNING AND DRESSING GRAPE VINES.

YOUR correspondent “Ipswich” is good enough to commend my article on this subject (page 523), but criticises some of my observations, and also indulges in a little mild form of humour at my expense.

What I term “miniature sap reservoirs” are badly ripened laterals, these being disbudded to one or two buds, the latter thus being greatly assisted by the stored-up sap that has never solidified. If we cut away these laterals we not only destroy the sap contained in them, but the Vines also lose much more by bleeding. Soon after the Vines are well into growth I have found these disbudded laterals perfectly dry, and if they have not acted as “miniature sap reservoirs” what has become of the sap? What would “Ipswich” do with badly ripened Vines, say any which if pruned at the present time would at once start bleeding profusely?

I am of opinion that very little is gained by cutting a large bud in the case of such free-fruited sorts as *Black Hamburgh*, as those smaller buds nearer the base of the laterals will, if the sap is concentrated on them, give quite as good bunches—I might say better, if somewhat smaller, as they are frequently more compact and handsome. The larger buds may perhaps produce a stronger growth with possibly a greater number of bunches, but this and the presumably stronger root-action are doubtful gains. It will be seen my argument is that the character of the bunches is not wholly determined by the parent leaf, but is rather determined by the pruning and amount of stored-up sap. I like to prune to a perceptible bud, this sometimes being an inch or more from the rod, sometimes less; and other conditions being favourable, this comparatively small bud

developes into a good fruiting shoot. If we did not prune to near these basal buds it would be found if they break at all they would seldom produce bunches. The passage, therefore, relating to this part of my subject, and which "Ipswich" selects as serving to confute my own argument, really does no such thing—at any rate I fail to see that it does. That the terminal bud will in every case break the strongest I do not dispute, but repeat that this is due to the concentration of the sap rather than to the superior size of the bud. Perhaps I did not write plainly, but I cannot help thinking the sense of my remarks might have been evident enough to "Ipswich."

I must admit having a good laugh at the way in which "Ipswich" treated my remarks upon the clay and tar dressing. I certainly ought to have remembered how differently we are all constituted, and that what is agreeable to one is decidedly obnoxious to another. For my part I am so well pleased with the simplicity and effectiveness of the mixture that tar is almost an object of veneration with me; and this ought not to surprise "Ipswich," since it appears that he, too, has had to contend with the much-to-be-dreaded mealy bug on Vines. I will, however, readily withdraw my remarks as to the superiority of clay and tar to all other mixtures as far as the obnoxious character is concerned, and content myself with describing it as the simplest and best remedy. Perhaps "Ipswich" by way of return will give us the benefit of his experience with mealy bug on Vines, as, although ours are clean, there are yet numbers of growers who might be glad to know the remedy he evidently considers superior to that with which we are so well satisfied.—W. IGGULDEN.

OUR ORCHARDS AND PARAFFIN.

ON page 526, under the above heading, your correspondent, "A Foreman," in detailing his method of mixing colza and paraffin oils, and applying the same, apparently indiscriminately, to a varied collection of orchard house trees, asserts "it (the oil) is not injurious to fruit or wood buds." Yet in the next paragraph I read, "If any of your readers would like to try the experiment I would advise them to 'taste and try' before they buy, and not endanger their crops and trees." Will "A Foreman" kindly inform your readers whether any Peach and Nectarine trees in the orchard house of which he speaks were dressed with the oil over old and young wood alike, and if so whether the "crop and trees" suffered during the following season in consequence of such dressing? To recommend in the pages of your widely read Journal such drastic measures (unless entirely justified by results) is to incur very grave responsibility, and is, I fear, very apt to mislead young beginners in spite of the saving clause "taste and try before you buy."—T. W.

SNOW'S WINTER WHITE BROCCOLI.

THE fact that I am now day by day cutting very beautiful heads of this Broccoli reminds me that I have an act of justice to perform to the firm of Messrs. Nutting & Son, seedsmen, of the Barbican, London. In the *Journal of Horticulture* at the end of 1882 I called attention to what I considered a likeness between Veitch's Self-protecting Broccoli and the variety of Snow's Winter White Broccoli that I used to know about twenty-five years ago. There appeared to me a great similarity both in manner of growth, time of coming in, and character of heads, and I could not resist saying so in the Journal. During the week following I received from the Editor a packet of seed with the following explanatory note: "Sir,—We enclose a small packet of Snow's Winter White Broccoli that your correspondent 'P.' will find, we believe, the same as he knew twenty-five years ago. We should like him to try it.—Yours obediently, Nutting & Sons. December 7th, 1882." Well, I sowed this packet side by side with my other Broccolis, and especially with a sort of Snow's that a brother gardener told me he had direct from Wrest Park, where Snow's Broccoli originated. These two are exactly alike in manner of growth, time of coming in, and form and colour of heads, and are, I firmly believe, the real old form of Snow's Winter White Broccoli. Anyone who has grown Snow's Broccoli will have noticed that from however pure a strain of seed (I noticed this peculiarity in the olden days) there are plants with slight differences of growth, both as to form and the wrapping-up of the flower heads. Some are paler in colour, grow more upright, and wrap the flower heads with a twist or corkscrew-like arrangement of the leaves; others are more spreading in their growth, are of a deeper green colour, and the centre, where the flower head comes, is arranged simpler as to the disposition of the leaves. It is difficult to describe on paper just the precise differences there are between these two members of the same family.

Now, Veitch's Self-protecting Broccoli appears to me to be a well-selected form of the pale-coloured twisted-centred Snow's. I desire the above words "appears to me" to be italicised, in order to protect myself from the least suspicion of unfairness to Messrs. Veitch as to the origin of their Broccoli. I am, however, satisfied that the variety of Snow's Winter White Broccoli which Messrs. Nutting & Sons have sent to me is true; and I am confirmed in that judgment by one of the chief head gardeners of our neighbourhood, who walked with me through both plantations of Broccoli only the last week, and who was delighted to find that an old favourite vegetable was still to be had true as in past days.—P.

CATCHING MOLES.—More than a year ago I saw a book in a shop in Huntly entitled "Moles and Mole-catching," by the mole-catcher to

His Grace the Duke of Devonshire, Chatsworth. Although only about the size of a child's primer and of twenty-six far from closely printed pages, I at once bought it, the price being 1s. It tells of the habits, food, and breeding of moles, &c. As it was the catching that I was most interested in, I saw the leaves turning over too fast for much to be given about the mode of catching. On coming to the last paragraph it had these words: "We shall not attempt to give full instruction how to catch them, as no one will expect more for the price of the present book; neither would it be fair or reasonable in the interest of men who, like ourselves, have given time and money to learn the business, and are dependent upon obtaining a livelihood from it. . . . Therefore, we shall not be considered uncharitable if we stop here." Have you ever read anything like the above? I never did. It is wide asunder as the poles from the mode of teachings of the *Journal of Horticulture*. Can any of your readers give us an article on how to catch moles, or tell of a book that gives the information?—JAS. SHEARER, Cairnie.

EUCCHARIS SANDERIANA.

FOR this beautiful stove-flowering plant we are indebted to the enthusiasm in the work of plant-collecting and introduction exhibited by Mr. F. Sander of St. Albans, whose labours are devoted almost as much to the discovery of useful plants generally as they are to that of Orchids. Mr. Sander has been instrumental in bringing within reach of English plant-growers many plants of first-rate quality, and among the best of these must be numbered the Eucharis to which his name is attached. The disparaging comments to which this Eucharis has been subjected by several writers are perhaps a little premature. We have not had the plant long enough to warrant us in giving a decided opinion of its merits as a garden plant when compared with the well-known *E. grandiflora*, better known as *E. amazonica*. The capabilities of a plant are not always fully revealed under the treatment to which it may be subjected when first introduced. It would not be difficult to point to many instances like this, and in the case of many plants, the qualities of which are now generally admitted to be first-rate. What has been said against *E. Sanderiana*, however, is quite exceptional when weighed against the high encomiums it has won from others, and so far as our experience goes this Eucharis is destined to become a great favourite. "Comparisons are odious," and the condemnation of new plants because they are not apparently as good as old ones is but a poor way of measuring the worth of the new-comers. Judged by what is at present known of *E. Sanderiana*, apart altogether from what it is when placed by the side of other species, its free-flowering character, the beauty of its blooms, and the ease with which it may be grown and flowered without any extraordinary or "special" treatment, are such as should recommend it to all growers. Already the same plant has bloomed three times in one year, and the flowers have lasted as long, both on the plant and when cut and placed in water, as other Eucharis flowers do. For *E. Sanderiana* precisely the same treatment as that given to *E. grandiflora* will be found most suited; indeed, we may say the whole of the known species of Eucharis require the same treatment as regards soil, temperature, and water. It has been said of this new species that its capabilities will not be properly known until it has been tested by the market growers, and without endorsing this view we may say that the effect of liberal cultivation may be to reveal even better qualities than those our at present short acquaintance with it has brought out.

We cannot do better than quote Mr. Baker's descriptive remarks on the botanical characters of this plant. He says:—"This new Eucharis will no doubt be a very popular plant. It has completely the habit and foliage of the well-known *E. grandiflora*, but the corolla is almost entirely adnate to the dilated upper portion of the perianth tube, leaving only a narrow collar-like free border, upon which the distinct portion of the filaments is inserted. It comes from the same country as *E. grandiflora* and *E. candida*—viz., New Grenada." The flowers are pure ivory white with yellow filaments, and are borne on a scape some 15 inches in length, strong scapes bearing about five flowers each. So far the flowers have been produced in the winter months.

Before leaving this subject a few words on the cultivation of Eucharis grandiflora may prove useful to those whose success in its management is not satisfactory. The most suitable compost may be formed of strong rich loam two parts to one part of leaf mould and coarse sand, with a little decayed cow dung. The pots should be sufficiently large to allow the roots to ramble a little—say a 12-inch pot for half a dozen bulbs. The bulbs should be buried in the soil, the neck just peeping above the surface. Deep potting is one of the secrets of Eucharis culture. The drying-off treatment has almost exploded, it having been proved that these plants do not require so much rest as such treatment would imply. A temperature of 65° to 70°, rising to 80° in summer, will be found best suited to these plants. After flowering water should be withheld for a week or two; at all other times a liberal supply is necessary, as these plants are always growing. Where grown in large quantities the bulbs are often planted out in beds beneath which hot-water pipes are placed, but as good results are obtainable if the bulbs are kept in pots and plunged in a tan or dung bed. If potted in good soil in the first instance it will not be necessary to do more than top-dress the plants annually, repotting only when the bulbs are overcrowded. Liquid manure may be given when the flowers spikes begin to appear. If placed in an intermediate house to develop their flowers a longer display and blooms of better substance will be the result.

E. candida, about which there are many conflicting opinions, owing to its having been confused with the *Calliphrurias*, to which it bears a

close resemblance, is a distinct and beautiful species, yielding under good culture several crops of flowers of the purest white. When well grown the scapes bear as many as ten flowers each. This plant was introduced in 1851 by M. Linden, but disappeared shortly afterwards to be replaced by a species of *Calliphrya*—*C. subdentata*, which was introduced as the lost *Eucharis*, and for a long time was cultivated as such. As a garden plant it is much inferior to the *Eucharis*, and, moreover, is rather difficult to flower. Mr. Bull in 1879, and Mr. Shuttleworth

large growers the Auricula and Carnation shows would lose much of their attractiveness. But what, I take it, "X." complains of is that large growers compete in classes where they really ought not to be. What does Mr. Douglas say in reply? "In order to keep the *great growers*" (the italics are mine) "*from competing against the smaller ones*," exhibitors in classes A and B cannot compete in C and D." But has this been found to be the case in practice, in the Auricula Society at all events? I have before me your issue of May 3rd last, in which your

FIG. 8.—EUCCHARIS SANDERIANA.

more recently, succeeded in obtaining bulbs of the true *E. candida*, which is now becoming as popular as its merits deserve.—W. K.

[For the woodcut (fig. 8) representing a plant of *Eucharis Sanderiana* in excellent condition we are indebted to Mr. W. Bull, King's Road, Chelsea.]

SPECIAL SOCIETIES.

I FULLY agree with the principles enunciated by Mr. J. Douglas on page 14 as to the undesirability of creating a monopoly for inferior productions. I concur with him that were it not for the support of the

esteemed contributor "D., Deal," writes on the Auricula Show as follows:—"In the class for four and pairs there were eight exhibitors, although I cannot but think unfair use was made by some exhibitors of the classes. I have said that in the classes of four and two plants exhibitors showed who I do not think in all fairness ought to be there. When one states that 'he' has an over-stock of 1000 plants that he wants to dispose of, it cannot but be that he must swamp the young exhibitor who, with his forty or fifty plants, is desirous of gaining a prize. When classes are made for the special purpose of allowing small growers to compete, I hardly think it is desirable for the large growers to enter."

These extracts speak for themselves, and really bear out the complaint.

of "X." that the regulations do not hinder a few growers sweeping off all the leading prizes. There should be some rule to prevent such a state of things, and Mr. Douglas will at once see the justice of this suggestion. I wish the Society every success, but such matters as the one under notice do much to cause distrust and dissatisfaction in more quarters than one amongst would-be supporters and exhibitors.—AURICULA, *North London*.

I DO not wish "X." to think that I take exception to anything he or she may be pleased to write. If "X." writes for information why should anyone take exception? I would like to know who are the numerous growers that are fearful lest the expenditure on the special societies will be greater than the results obtained. They are evidently not members of the societies, at least I think not, else why should they go to "X." about it instead of expressing their alarm at the meetings of the societies? Those who undertake the management of the societies are surely not expected to make any guarantee of that kind. I am sure I never gave it a thought. "X." is also fearful that the said societies are not of national utility. Dear me! why should they be of national utility? A few old fogies are fond of Auriculas, Carnations, &c.—so very fond of them that they go to the trouble to promote special exhibitions of them, thinking that a certain portion of the public would be pleased to see them. The public, or at least a portion of it, see and applaud. The fogies are satisfied, and do not trouble their heads about "national utility." Special societies, or any kind of societies for that matter, always increase the number of growers; it is in the nature of things that it should be so. Surely no reasonable person need ask for "conclusive evidence" upon what is well known to be a matter of fact. Whether it is "commensurate with the outlay" is another thing.

Your correspondent devotes a few lines to criticising the schedules sent to him, and gravely asks why in certain classes "one grower is allowed to take all the prizes offered?" That is just the very thing he cannot do, although he has a chance to try. If he were successful in doing so the defeated exhibitors would carry him shoulder high round the building, and the victory would be proclaimed from Land's End to John o'Groat's. Fancy one man taking thirty-two prizes in four classes! They are the most interesting part of the exhibition, and no exhibitor that I am aware of ever asked to have them altered. I expected "X." would have sent me his name and address, and would have made some useful suggestions, but I am much disappointed.—JAMES DOUGLAS.

CHOU DE BURGHLEY.

I AM pleased to find your three correspondents are of one mind as regards the subject under notice. On page 511 of your issue for December 13th we have it clear that Mr. Abbey's experience respecting this vegetable has been formed during the present season, for he says:—"I thought if Chou de Burghley were no better than these it were poor indeed; hence it was through prejudice condemned before trial, and I certainly was not prepossessed in its favour by what others had to say in its commendation. To solve matters to my own satisfaction I procured a packet of seed, sowed part in March and part in April." This, I presume, was March and April last. Previous to this Mr. Abbey appears to have regarded his now favourite vegetable as a "bastard," and identical with those we are all accustomed to find amongst Broccoli. On page 4 Mr. Abbey says:—"Lastly I may inform 'A Working Man' that I have been acquainted with Chou de Burghley since 1878, when it was awarded a first-class certificate by the Royal Horticultural Society, and there surely has been ample opportunities of testing its hardiness since; but it is only this season I gave it a fuller trial to test its merits." What I had was the true variety, and, as before, I repeat it is a coarse vegetable. I never for a moment suspected Mr. Abbey to be a "cook," but I know that most gardeners are equal to the occasion when required. I am quite willing to admit that I am in no way capable to judge the merits of this wonderful Chou de Burghley if such delicious Cabbages as Ellam's Early, Little Pixie, and Coleworts are so strong-flavoured as to impair my taste. How many tastes have been impaired, I wonder, before Chou de Burghley came into existence with its strong flavour?

As to the time of boiling, it appears to me that Mr. Abbey and your other two correspondents possess 'cuteness far exceeding that of "A Working Man," or even the raiser, for they have been 'cute enough to discover how to boil it as "tender as a chicken" in thirty minutes, while the raiser cannot manage it in less than "one hour and twenty minutes," according to his statement in a contemporary.—A WORKING MAN.

THIS vegetable has been duly criticised, much praised, and even abused. Making much allowance for latitude and nature of soil I thought it unfair to give a verdict on its merits before this season. But now having tested it I am of opinion that it is an excellent vegetable, not at all unlike the Couve Tronchuda when properly cooked; and so far as its requiring one hour and a half to boil till soft and melting as marrow, only half an hour was allowed here, which cooked the heads to perfection. The Broccoli in the centre was formed about the size of a small egg, and of a decided Broccoli flavour. I never doubted what Mr. Gilbert said regarding his novelty, but believed it quite possible that Chou de Burghley might change its character in our soil and climate. Mr. Gilbert has several times favoured us with samples of products, and notably with a number of varieties of Melons raised by him, all of which were equal to what he described them to be, his selection of Victory of Bath being equal to the best Melons I had tasted before and since I received that kind from him.

With vegetables much depends on the cooking, and the most and best cooked vegetables may be met with in noblemen's and gentlemen's houses, where it is not uncommon to leave that important business to underlings who have never seen vegetables properly cooked, hence a bad name is given to really valuable articles, Potatoes especially. The Chou de Burghley here was placed in boiling water after the heads had been well washed in salt and water, and half an hour afterwards they were strained and served. Some weeks ago they probably would have required more boiling.—M. TEMPLE.

BOTHY LIFE—ROOMS AT KEW.

THE Editor of the *Journal of Horticulture* deserves the thanks of all for allowing the grievances of the young gardeners at Kew to be fully stated. These grievances are by no means of an imaginary character, as anyone may prove who will take the trouble to make inquiries. Whether the remedy should take the form of a bothy or an increase of wages is, I think, open to discussion. It is a most unwarrantable assumption on the part of "Boss" to suppose that these thirty men could not be housed together without making a sort of pandemonium. "Boss" would do well to remember that they are governed by stringent regulations. It is not necessary to commit a great offence to insure a severe reprimand, generally accompanied with the intimation that the second offence will terminate further service in the garden. The young men accordingly adapt themselves to the rules or the establishment, and there is no reason to suppose that they would not be equally attentive to bothy regulations, as the foreman might with advantage act the part of monitor. As to the moral side of the question, in my opinion it would be a decided improvement, for the habits and characters of some of the people that many of the young men are compelled to lodge with are very unsatisfactory. There is one thing in connection with a residence for the young men that would prove an immense benefit to their mental and physical health—I mean a good bath. This could be easily and cheaply constructed. An ample supply of water is obtainable, and this, together with well-cooked and wholesome food, would assist greatly in preventing the frequent loss of health that many suffer who go to Kew for twelve or eighteen months. On the whole I am inclined to think a bothy would act well and be of great advantage to the young men. In the absence of such accommodation the wages should be increased. The effect of the present rate of wages is to virtually exclude a numerous body of deserving young gardeners—i.e., those who cannot draw upon their relations or friends.

In my opinion it is a mistake to admit very young men to Kew. I am convinced that older men, say from twenty-two and upwards, would be in every way more satisfactory, as the special knowledge obtainable at Kew would be far more valuable as a finish to a gardener's education.

Will "Libertas," who defends the existing system, undertake to prove that 16s. per week at Kew are equal to 16s. in a private establishment? Assuming that 16s. with bothy, vegetables, and frequently milk and other advantages, is the average remuneration of young gardeners, a reduction of at least of 6s. will have to be made on going to Kew to balance these. "Libertas" says that the young men are transferred from house to house for their own benefit and to the disadvantage of the plants. To my certain knowledge that is done very irregularly, some young men receiving two or three changes, others only one, and some none at all. In short, this so-called shifting from house to house only occurs as vacancies arise, and as there are over thirty young men such a method is manifestly unfair to many.

As to the science lessons, the excellent intentions, and commendable efforts of the authorities are rendered less useful than would otherwise be the case owing to the time at which the lessons are given. It should be borne in mind that most of these young men are confined to tropical houses, which is very well during the winter months, but quite different in the summer. For instance, every young man is confined to his respective house for five hours at a time—viz., from 1 P.M. till 6 P.M. during the summer months, and mostly, be it remembered, in high temperatures and humid atmospheres. After they have passed through this energy-destroying process they have to attend lessons on botany four or five nights every week. This is not all, for these lectures have to be written out afterwards, and it is difficult for young men to grasp even the rudimentary facts of botany under such circumstances.—SCRUTATOR.

To become a good gardener we may, I think, safely assert that young men must not only study their work during the hours of labour, but also more especially in their leisure hours. In fact more depends upon how these leisure hours are spent than many of us were at one time aware of, or possibly we should have acted very differently. By having rooms or sharing a bothy with others in a garden, young men, besides being able to attend to their duties, also have a much better chance to improve themselves. If they fail in this respect they have only themselves to blame, at any rate they cannot blame employers who have done their best for them. That in some cases the young men are only kept in order by the head gardener or even the foreman must be admitted; but this is no argument against the necessity for bothies, indeed it only serves to convince us of the good policy of providing rooms where they can be so controlled. Lodgings are distasteful to many young gardeners who have previously lived in bothies, and when these lodgings are expensive, not of easy access, and otherwise objectionable, there is all the more reason why more suitable lodgings should be provided, especially seeing that such generally prove advantageous alike to the employer and employés.

I have always been an admirer of Kew Gardens, and rarely miss an

opportunity of spending a few hours among the wonderful collection of plants there cultivated. I have noticed that many of the young men here employed are very intelligent, and all, I presume, apply for the appointments with the motive of availing themselves of the unequalled facilities for becoming well acquainted with the culture of plants. Out of the gardens there is every inducement for them to do as other young men do—viz., spend their time in a manner by no means conducive to the formation of clever serviceable experts such as we expect to be turned out by Royal Kew. I maintain that for these young men to be exposed to the discomforts as well as the dangers attending the class of lodgings many of them inevitably obtain is, to say the least, an oversight on the part of those responsible. It is not the want of means or of a suitable position that can be pleaded as an excuse for not making suitable provision for them, and unless I am much mistaken no great opposition would be met if someone in authority took the matter up. For the good of all concerned I trust this benefactor will soon take the preliminary steps towards obviating the present unsatisfactory state of affairs, and by so doing gain the esteem of many present and past Kewites.—A HEAD GARDENER, *Somerset*.

In answer to your correspondent "Boss," under this head, I venture to say that if he had had experience of the Kew gardeners' lodgings he would not consider the matter of trivial importance, and my opinion is formed after several years' service there; for a new comer to the Gardens is seized upon the moment his wants are made known by persons who receive a trifling recompense from certain lodging-house keepers, some of whose tenements are by no means of an enticing appearance to young men, especially those from the gardens of the nobility in the United Kingdom. I can further add there has been for a number of years a room set apart in the Gardens where the young men can rest assured no attractions of a fancy fair will upset their studies during reading-room hours. There are two resident foremen, who with the young gardener who acts as librarian, are responsible for the behaviour of attendants, but complaints are exceedingly rare. Undoubtedly similar measures could be adopted in a so-called barracks should the authorities give the matter the attention it deserves.—ANOTHER EX-KEWITE.

WINTER-FLOWERING CARNATIONS.

THE time for propagating these has arrived if large and strong plants are to be had for next winter's flowering. I find the cuttings strike very freely when taken off about this time and dibbled into sand in the propagating house. They form roots in about ten days or a fortnight. When rooted the plants are placed into 2½-inch pots in light soil, in which they root quickly, and are then removed into a cooler pit and kept near to the glass. As soon as the plants are large enough the point of each is pinched out, which causes them to break low down, and lays the foundation for sturdy-growing plants. In March they are shifted into 4-inch pots, this time employing loam and cow dung in the proportion of three of the former to one of the latter. We pot rather firmly. In April the plants may be removed to cold frames, and in May and throughout the summer the sashes are kept off the plants. Very good plants may be grown in 6-inch pots. Bone-meal as fine as possible may be added to the compost recommended above. Again pot firmly. The only attention required throughout the summer and autumn is to keep the soil in a moderately moist condition, and put stakes to the advancing flower spikes as they require them. In October the plants are taken into their flowering quarters, and require little forcing until about Christmas, when we find a good heat necessary in order to induce the flowers to open and others to come on.

It is through the winter months that the advantage of firm potting is most seen. With occasional surface dressings of artificial manure the plants continue making roots, which enable them to keep on forming buds and opening flowers in succession for several weeks. The one insect which I find injures the plants is green fly; occasional fumigating keeps it in check.—B.

A NOTE ON CABBAGES.

FOR several years I have allowed the spring-cut Cabbages to start into growth and form several small heads, which came in very useful through the summer and autumn months. This is a plan which is carried out by very many gardeners, and in some respects it is a good one. But it has this serious disadvantage, that the soil is very much exhausted after the Cabbages are removed, and the crops that follow suffer in consequence. It cannot be for the want of manuring in our case, as we employ above the average of cattle manure, and in addition dress with so-called artificial manures. In future I intend to remove the plants as the crop is cut, and plant more frequently.

In order to bring the crop in quickly it is a good plan to give each plant a dressing of a spoonful of guano; sulphate of ammonia is also of great value as a dressing, about half the above quantity being sufficient. Gardeners will find the latter a much better stimulant than nitrate of soda, which passes too quickly out of the soil, while the sulphate acts more slowly, and remains of utility as a plant-food for a much longer period. If the weather is warm in February that is quite early enough to employ any of these manures. Much depends on the variety grown whether we get Cabbages in quickly in spring or not, and the same remark applies to spring plantings to come on after the spring cuttings are past. One of the best I have tried is Nonpareil Improved, a medium-

growing sort, which hearts very quickly, and is also good for succession crops. Mein's No. 1 Cabbage is also very good for northern localities. One of the best from a gardener's point of view is Little Pixie, which, in addition to occupying very little room when growing, turns in very quickly, seeds sown in March coming in for cutting in the end of August and later. A pinch of seed sown in a frame in the beginning of February yields plants that come in about as early as the larger kinds which are sown in autumn. I do not find Coleworts succeed in our northern latitudes. A late Cabbage which comes in about October and November is the Winningstadt. Some sow the seeds of this in autumn, but I sow in early spring. Though not a Cabbage which can be recommended for the dining-room, it is serviceable for the servants' table.—EAST LOTHIAN.

PROTECTING PLANTS FROM FROST.

THE effects of the present mild weather, with the disagreeable accompaniment of heavy rain and dense black fogs, upon vegetation are giving rise to some anxiety in the minds of many gardeners. If, after the spring-like mildness and excessive moisture of the winter up to the present, we are visited with sharp frosts and cold winds, much disaster will result, and that in spite of the greatest care in matters of protection exercised by careful cultivators. With seasonable weather we should at this time of year have the whole of our tender plants in their winter covering. The present mildness, however, forces many plants into activity which if continued must inevitably be followed by fatal consequences, unless we have no cold weather this winter, which is more than we dare hope. Trees and shrubs are bursting their buds, bulbs are pushing through their earthy covering young and tender leaves, and all around us we see a bursting into life which is unseasonable in the middle of January, and is what we should look for only in March or April.

It will be necessary for those who are anxious to prevent any serious consequences to take all possible precautions against the cold winds and frosts. At the same time every care must be taken that we do not assist by too much coddling the work of destruction which cold would bring. It is too frequently the practice to set about the work of matting, strawing, and covering all tender plants as soon as the cold weather may be expected, and although much may be said in favour of such a practice, it is unfortunately too often the case that harm rather than good is done by it. As an instance of this may be mentioned what occurred last year when we were visited with weather of extraordinary mildness during the greater portion of the winter, followed by sharp frosts at the commencement of spring. As usual, the most tender plants were covered sufficiently to prevent severe frosts from injuring them, and this covering was allowed to remain all through the season until all danger of cold weather had passed. The result of this was, that what with the warmth of the earlier portion of the winter and that afforded by the covering, many of the plants were fatally injured, some of the most herbaceous had perished altogether, and the effect of the spring cold upon many others was soon apparent in the shrivelling of the young leaves and the weakness of the flowers. It was plainly evident that in our attempts to keep out the cold we had done much harm, and that if the plants had been left without covering until it was really required little or no harm would have been done. A little wholesome severity is often better for many plants than indiscriminate protection, which too often renders the plants delicate and incapable of bearing the slightest cold. We are, perhaps, a little too apt to afford protection to plants without making any allowance for the capacity of the plants themselves to adapt themselves to circumstances. Protection for plants should not be resorted to unless it appears really necessary. The material used for protecting plants from the effects of cold is too often conducive to ill results. To straw and mat, or cover with leaves or such material as holds water, plants which naturally have the whole of their branches and stems exposed to the influences of the air and light, is analogous to burying them, and as likely to prove injurious to their health as such treatment would be if practised upon animal life. The protection we are compelled to give many outdoor plants is a necessary evil, unavoidable to a great extent in this country. That something should be done to prevent tender plants being injured during severe weather must be admitted, but it should be done with due consideration. When such means of protection as those mentioned are used they should be removed again as soon as the danger has passed, and be replaced and removed again as often as necessary, at least in the case of those plants which would not stand a long covering without injury.—W. K.

BORNEO.

[THE following is the substance of an instructive paper upon the productions and government of Borneo, read before the members of the Horticultural Club, Henrietta Street, Covent Garden, London, on the 8th inst., by Dr. Houghton, who has resided in that island during the past twenty years.]

It is, of course, familiar knowledge that the island of Borneo is situated in the China Sea, about 450 miles east from Singapore, and is therefore a tropical country. It is supposed to be, next to Australia, and probably New Guinea, the largest island in the world, being more than 800 miles in length by about 600 miles in width. The total population of the island is estimated at nearly two millions, comprising a great variety of races and

aboriginal tribes, and consist of Chinese, who migrate there in large numbers; Malays, who are supposed originally to have come from Sumatra; Dyaks, Kyans, Malinowes, Punans, Pakatans, Ukits, and others.

The Chinese constitute the principal trading and labouring part of the population. They have established bazaars in many parts of the Sarawak territory; they purchase produce from the natives in all parts of the country, and do all the export and import business. Some of their merchants are very wealthy, and have lived many years in the country.

The Malays also do some trading, chiefly along the coast and with adjoining islands, but they are mainly occupied with agricultural pursuits, such as the cultivation of Sago, Tapioca, and Rice, and are the most numerous race in the country.

The Dyaks are of two kinds, Land Dyaks and Sea Dyaks.

The Land Dyaks, so called from their living in the interior, are principally engaged in working gutta percha, which they obtain from the trees, which are indigenous and grow in the jungle, and sell to the Chinese merchants. They also do some planting, but mostly Rice for their own consumption, though they sometimes sell the surplus. They are a somewhat feeble race, and are thought to be gradually dying out.

The Sea Dyaks are a finer and stronger race, living on the rivers and by the coast. They also work and sell gutta and plant Rice, but in addition weave cloths for apparel, work in brass, and make for their own wear rings, anklets, and other ornaments, being very fond of decorating their person.

Of the other races inhabiting this interesting country the Kyans come next for notice, and form a marked contrast to the Dyaks. They are more peaceful in their habits, live more in the interior, and construct dwellings which are models of cleanliness and comfort. These dwellings are built of bilian or ironwood, and often of large dimensions, many possessing as many as thirty or forty "doors," a term used to signify a part of a house occupied by a separate family. These, and nearly all dwellings in the country, are built on piles from 6 to 12 feet or more from the ground as a protection against snakes and other vermin, and in olden times from night attacks from hostile tribes. They consist of only one floor with sometimes a loft over.

The Kyans are chiefly engaged in agricultural pursuits, but some of them are clever in brasswork, and others in wood and ivory carving. The women have a curious custom of wearing heavy rings with leaden weights attached in their ears, until the lobe hangs down on to the shoulder, which is considered a mark of great beauty.

The Malinowe race is not very numerous, and they are chiefly occupied in the cultivation of Sago and Rice. They are very peaceable, but have a curious custom of flattening the heads of their newly born children by fixing heavy boards upon them in such a way as to prevent the rounder formation of the cranium which we think more preferable.

Of the other races I have mentioned but little is known, and the only peculiarity calling for notice is that the Ukits, who inhabit a remote part of the country, and are as yet in an uncivilised state, may be said to possess no earthly habitation—that is, they build no houses or other dwellings on the ground, but construct their domiciles on the branches of trees. My brother, the late Alfred Robert Houghton, who lived amongst them as Resident of the district for some time, and did not find them at all a savage race, but rather amiable than otherwise. He endeavoured to teach them to construct buildings more adapted to human wants, but he did not stay among them long enough to make much progress with the work, and I have not heard what has been done in the matter by his successors in the residency.

The climate on the whole is extremely healthy though warm and moist, and Europeans may reside there with comfort and retain their health for many years, as evidenced in my own case, with care and proper precautions suitable to a tropical country. The temperature ranges from 69° to 80°, except in the hottest seasons, and then it seldom exceeds 90°. There are two monsoons—the N.E., which commences in November and lasts till March, and is the wet monsoon; and the S.W., which commences in April and lasts till November, when the weather is usually fine and dry, June and July being the hottest months.

The agricultural products are Sago, Rice, Tapioca, Gutta Percha, Indiarubber, beeswax, edible birds' nests, Gambia, Pepper, &c. An attempt is being made on an extensive scale to grow Cinchona in a locality thought to be suitable, which promises to succeed under the auspices of the Government and the able superintendence of a planter from Ceylon, but the trees are not yet sufficiently grown to yield any product of quinine. They are doing, however, remarkably well; the climate and soil seem to suit them, and there is every prospect of the plantation

becoming the nucleus of an important addition to the already rich produce of the country. Experiments are also being made to grow Cocoa and Tea, but only at present on a small scale, though both are promising well. Liberian Coffee has lately been extensively planted, and is also likely to succeed. The soil and climate seem to be suitable, and when I left Sarawak the trees were growing well and showing much promise. This experiment is watched with much interest, and the cultivation is likely to extend over large areas if it prove a success.

The fruits indigenous to the country or found to grow there well are Mangosteen, Durion, Lancat, Pumillo or Shaddock, Mangoes, Rambutan, W. E. Pines, Oranges, Lemons, Custard Apple, Jackfruit, Breadfruit, Banana, Roakam, Papaya, Kayminton Nut, Gadus or Cachu Nut, Katapong, Melons, Limes, &c. Most of these I have grown in my own plantation to great perfection.

I have also tried and succeeded well with the following vegetables from seeds supplied me from England by Messrs. Sutton and Sons. Vegetable Marrow, Celery, Broad Beans, French Dwarf Beans, Cabbages, but without hearts, Lettuce, Watercress, Peas, Kohl Rabi, Onions, Radish, Endive, Asparagus, Beet, and some others; but the climate does not suit Grapes, Peaches, Plums, Apples, Pears, or the English bush fruits or Strawberries; nor among vegetables do Scarlet Runner Beans, Brussels Sprouts, Scotch Kale, Seakale, Savoys, or Artichokes grow well.

The flowers I have grown are of Roses the Tea sorts, including *Maréchal Niel*, *Gloire de Dijon*, and many others, all of which did well and flowered in great profusion. The soil, however, being sandy, had to be strengthened with burnt earth and cowdung for the better sorts; but there are many beautiful kinds growing almost wild which attain a great size both of flower and tree, and whole hedges may be seen covered with a profusion of flowers scenting the air with their perfume. I have also grown from English seeds or bulbs plants of *Portulaca*, which does splendidly, *Phlox*, *Lobelia*, *Petunia*, *Pelargonium*, *Gladiolus*, *Begonia*, *Gloxinia*, *Eucharis*, *Coleus*, *Bougainvillea*, *Balsam*, &c., besides native flowers innumerable, the names of which it would take too long to enumerate, and others imported from India and elsewhere. The Pitcher plant or Monkey Cup grows in great variety and to a large size, some of the flowers holding as much as a pint. The *Caladium* also grows well, and *Coleus* and *Begonia* are found growing wild on some of the mountains. Ferns I need not say grow in immense variety and to perfection, while Orchids of every kind and hue flourish in abundance, having found there a natural home.

ALTERING THE NAMES OF CHRYSANTHEMUMS.

I AM glad to find that this unjust practice of re-naming Chrysanthemums is being exposed, and I am quite certain many cultivators will hail your correspondent's letter as a very useful one, touching as it does upon a subject which requires ventilation; still it is somewhat surprising that no further correspondence has appeared in your valuable paper upon the matter. I quite agree with Mr. Payne that unless some steps are taken to check this fast-growing evil great disappointment will be caused both to the professional and amateur grower.

It is, for various reasons, most essential that when once a new variety has been named by the raiser it should always be catalogued and sold under that name. For instance, an exhibitor may be disqualified for having two flowers alike on one stand, both of which he has purchased this season at different houses under totally different names; for the one he has to pay 5s., and the other he obtains for 1s. 6d. I have before me several catalogues of the leading dealers in Chrysanthemums, and regret to say there are very few of them that are correct.

It would be a great convenience to all Chrysanthemum growers who, like myself and the members of the Society to which I have the honour to belong, are desirous of having their plants true to name if a complete list could be published of all Chrysanthemums which have been re-named, or had their names altered in any way, and I for one should have very little difficulty in pointing out a very large number that have been treated in this way.

One French firm informs me they have succeeded in raising forty-one new varieties, which will be sent out this season, and I trust that when they reach the English market and appear at the various exhibitions in the autumn we shall find them under the names given them by this French firm. I may say that our Society has resolved to ignore this re-naming, and exhibit our plants and blooms as far as practicable under the names given them by the raisers.—GEO. S. ADDISON, 22, Peckham Grove, S.E., Hon. Sec. *Lambeth Amateur Chrysanthemum Society*.

MR. HARMAN PAYNE's remarks in your issue of the 20th December appear justified by the facts of the case as it is stated, but seem to me to be incomplete, conclusive evidence being needed of the existence of the transactions indicated. Changing the names of plants is unfair to purchasers, and must result in utter confusion and prove inimical to trade. Messrs. Delaux et fils are deprived of their proper and well-earned reputation if the names of their varieties are altered. Are these

alleged "changelings" charged a higher price than the originals? Altering names is not, I fear, restricted to Chrysanthemums alone, but applies particularly to vegetables. In this latter class it would be interesting to know how many aliases some of them have. The trials at Chiswick prove what I have stated; but still the thirst for novelties goes on, and the public palate has to be assuaged with novelties only in name.—V., *Edinburgh*.

Your correspondent, Mr. C. Harman Payne, has taken a wise course in making public a grievance which I am sorry to say is very common at the present time among a certain class of growers—viz., sending out wrongly named Chrysanthemums. Why it should have existed so long I fail to see, but if all who have been victimised were to protest as well as he the practice would soon become a thing of the past. Nothing is more annoying than to grow for a whole season plants that were believed to be true to name, and then to find them inaccurate. I have experienced a little of this annoyance, and can understand the disappointment of others.

A year or two ago, wishing to renew my stock and obtain a few of the newer varieties, I wrote to a grower ordering about fifty varieties, which I did not receive until nearly two months after date of ordering. Of these not ten proved correctly named. Imagine my feelings when the flowering season commenced I saw Mr. Bunn transform itself into Emperor of China, Prince Alfred into Lord Derby, Criterion into—well, I know not what this would have turned into, as I had not the pleasure of seeing it in flower. It seemed an extraordinary variety; it grew for fifteen months without showing buds. The year following, more for curiosity than anything else, I wrote ordering a few more, but with much better results—only half were found to be incorrect.

I cannot see what advantage respectable firms who value their reputation gain by sending out wrongly named varieties, and do not believe they would knowingly send them out incorrectly named. Are continental growers from whom the English growers receive the plants as careful as they should be? Are the plants all they are represented to be? Blame at times is often thrown upon the wrong shoulders. Gardeners themselves might be more careful. I have often seen when the plants are potted singly small pieces of paper act as substitutes for labels, sufficient labels perhaps not being at hand.—C. WARING.

ADVICE TO YOUNG GARDENERS.

THERE is a striking contrast between the communications of your two correspondents, "A Working Gardener" and "H., Notts," on the above subject. "A Working Gardener" ably expresses himself in an excellent article, which deserves the attention of every young gardener; and if your correspondent "H., Notts," instead of writing in corroboration, had exerted himself in the commendable endeavour to finish the work commenced by "A Working Gardener," by pointing out the best way in which a knowledge of the subjects enumerated could be most advantageously acquired, he would have conferred a lasting boon upon the young members of the gardening fraternity.

It is certainly a fact that many of the young men spend their evenings in a very careless, not to say unprofitable, manner, thinking only of the time being.

If the desirability of studying the sciences—chemistry, geology, geometry, vegetable physiology, botany, and physics, as a scientific basis of gardening operations were pointed out in more forcible language than has hitherto been the case, I am of opinion that many more would make an attempt to acquire some knowledge of them than at present even know of their existence or meaning. I do not suppose the average young gardener knows what the various manures are composed of, or in what way they are beneficial to plant life; and is it not as desirable for the gardener to know that as for the physician to know what he is administering to a patient, and in what way it will act upon his system?

Nor yet, perhaps, do they know how plants obtain their food from the soil. That the application of manure is an essential operation is known from custom, but in what form it is assimilated by the plants is not generally known. I guarantee if the question were put to many the answer would be to the effect that it was brought about by an indescribable something, and they would not be able to explain the matter any farther. I consider the reason the sciences, chemistry, &c., are not more studied is because it is not generally understood that they are in any way conducive to the gardener's benefit, or they are looked upon as something entirely beyond the grasp of the ordinary intellect.

It is, as "A Working Gardener" observes, uphill work to pursue such study without the aid of a tutor, especially when the student is only possessed of an elementary education, as is the case with the majority of young men in gardens. But much may be done by application and perseverance, and it behoves any young man to apply himself solely to his trade or profession, be it what it may, making it his only aim if he would earn a name for himself in the world.

"A Working Gardener," in his excellent article, invites the opinion of many able writers when he says, "There are many amongst your correspondents who can better inform us how the above subjects may be most profitably studied and a knowledge of them acquired." I am sorry to observe that the invitation has not yet been responded to in a manner the subject is so well worthy of. I, for one, wish to thank "A Working Gardener" for his article on such a good subject, and I hope it will not be allowed to fall into obscurity again. I would gladly give any information if it lay in my power, but I come seeking advice and assistance instead.—QUERIST.

THE perusal of "A Word to Young Gardeners" in your issue for December 13th gave me great pleasure, and I am sure numbers of young men (myself included) will feel deeply grateful to "A Working Gardener" for his kind words of advice and encouragement. The recital of his experiences when a young man tends to interest and stimulate young men to strive to attain as high a mark as possible in the profession to which they have devoted themselves. No doubt the young men of the present day have many advantages which were denied our predecessors. During the last twenty or thirty years how many improvements have been wrought in the numerous branches of our calling, rendering the duties of a gardener less tedious than formerly. Amongst these may be mentioned the superiority of hot-water pipes over the old flues, the handy means of ventilation by using the simultaneous system as compared with the old method. But as the means have improved so also has the demand increased, and gardeners of the present day have much more to produce than formerly, and in proportion young men have more to learn; so in this age of competition it behoves young men to lose no opportunity of improving themselves if they wish to keep step with the advance of science. This may be done in numerous ways, such as attending evening classes, mutual improvement amongst themselves, studying the weekly and other horticultural literature, of which so much is now to be had treating on the different methods by which plants, fruits, and vegetables may be brought to perfection.

Reading frivolous exciting novels, to the exclusion of all beneficial books or papers, is a serious error into which a great many young men fall. This is a habit, and a most baneful one, which should and can be given up, as I know by experience. I would advise all who are given to such reading to quit it at once, and they will never regret it—at least, this has been my experience. Card-playing is another debasing game which ought to be discountenanced in all respectable circles, but one which I am sorry to say is very prevalent in bothies.

If young gardeners would only follow the advice given to them by such kind and experienced men as "A Working Gardener," how many future troubles and anxieties would be avoided. I trust that "A Working Gardener" may spend a happy new year, and long be spared to advise and encourage the rising generation of gardeners.—CALEDONIAN.

BATEMANNIAS AND COOL TREATMENT.

THE term "cool" as applied to the cultivation of Orchids is somewhat vague, and apt to prove misleading. The cool Orchid house of one grower may, and often does, differ as much as half a dozen or even more degrees as regards temperature from that of another. Some Orchid growers recommend a temperature of 45° to 48° during the winter months, while others prefer one of from 50° to 53° or even higher. It depends greatly on other conditions besides that of heat as to whether the particular treatment known as cool would prove suitable for the cultivation of many Orchids. Many growers are compelled to keep their cool house almost as warm as some would think sufficient for a Cattleya house, or, to employ another frequently used but almost as indefinite a term as cool—the intermediate house. From this it will be seen that many plants would thrive in the cool Orchid house of one grower which in that of another would soon perish. It is by far the best when giving cultural information upon Orchids, or indeed upon any plants, to state the temperature that is considered to be most suitable, and leave the reader to the choice of houses. It may be well to point out that in those cases where large numbers of the most popular of cool Orchids are grown there is no danger in keeping the houses at a uniformly low temperature; but where the cool house contains a mixed collection, and some of the plants are not well understood, it is far safer to keep the temperature at something like 50°. The coolest Orchids will not suffer under such conditions, whereas in the lower temperature many of those requiring a degree or two more heat would soon sicken.

I was led to make these observations by the remarks on Batemannias and their allies, page 555. It is there stated that "cool treatment suits most Batemannias," and "one of the chief reasons for failures is placing the plants in too strong heat, where they seem to make good progress at first but ultimately become enfeebled and collapse." Now the finest plants of the Batemannia, Bollæa, and Pescatorea family I have seen were grown in a warm house, where the summer temperature ranged from 70° to 75°, and in the winter from 55° to 60°. I have grown most of them, and at the present time have a good collection in my care. Last summer we placed the whole of them in an Odontoglossum house along with O. vexillarium and O. Phalanopsis. Here they grew freely. In the winter we have always removed them into an East India house, but this year, wishing to test their hardiness, I left them standing in their summer quarters. The result was that in a short time the leaves turned yellow and the hearts of two of the plants suddenly rotted. We at once removed the whole of them into the East India house, where they have almost recovered. This appears to me conclusive evidence of the injury caused by cool treatment to the Batemannia family.

The late Mr. Spyers, who grew these plants better than I have seen them with other cultivators, has made some excellent observations on their cultivation in his usual practical style, and which are in my opinion the most reliable information we at present possess on the management of these beautiful Orchids. He said "The plants—namely, Bollæas, Batemannias, Warscewiczella, Huntleyas, and Pescatoreas, grow in very shady woods in a country where rain falls more or less every day in the year, save five or six. It is easy to understand what difficult plants these are to get home alive; it is indeed rare in buying a bundle of imported ones to get more than a few live rhizomes. These

rhizomes should be immediately potted in crocks, placed in the East India house, and watered all over every day. Soon or never breaks will show. If they do show still continue the watering, and when roots appear give them a little peat and sphagnum to run in as soon as it is possible to recognise the dead from the living, place the plants in pots half filled with drainage, using peat and sphagnum with a small quantity of half-decayed leaves for compost. This mixture should be used for all future pottings or top-dressings. Established plants should now be placed in the intermediate house. Give them a position where they will be protected from even weak sunshine. All through the summer water copiously overhead every morning and evening, once a week give a good soaking direct to the roots. Towards the end of the year, when the end of the intermediate house night temperature falls below 60°, move the plants into the East India house, water overhead once a day, and at the root often enough to prevent dryness." I saw Mr. Spyer's plants at Burford Lodge in September, 1881, and they were then in splendid health, with leaves on them like flags, and flowers of the greatest beauty. It was here that I learned that the *Batemannias* and their cousins along with *Odontoglossum vexillarium*, *O. Phalænopsis*, and *O. Roezlii* could be grown into large specimens in this country under proper treatment. My experience, along with that of most Orchid growers, is that large plants of the Orchids above mentioned are exceptionally difficult to obtain and keep, which is due to their unfortunate trick of dying behind as fast as they grow in front.—W.

HISTORICAL JOTTINGS ON VEGETABLES.—No. 11. THE BEET.

THERE is some reason for the assertion that the Beet as a culinary vegetable scarcely has at this time the popularity to which its good qualities might lay claim. It is really much in the position of the Parsnip; yet this may not be entirely the fault of the public, though in this luxurious age the wholesome is often rejected for the toothsome. Perhaps the vegetable is insufficiently recommended to notice by growers and vendors. Our common name for it is evidently from the Celtic word *bett*, meaning "red," which affords an indication of the kind of Beet which was best known to our ancestors. The wild or Sea Beet (*Beta maritima*) occurs here and there on the coast of England and Ireland. The leaves have been eaten like Spinach. But most botanists are not of Bentham's opinion that the garden varieties are descended from this stock. There seems great probability that our cultivated Beet is a native of South Europe. Certainly the Greeks knew the Beet full well centuries before the Christian era began, and old authors mention a white and a black kind. Black, says Fée, we may presume was a purple or purplish red—identical, that is, with our red Beet. To the white Beet the appellation of "Sicilian Beet" was given, owing to the profusion with which it grew in that island, supplying the inhabitants during a long period of history with no small amount of the food they consumed. There is, however, a black Beet, and this with the others was figured by Matthioli in 1565, and he describes the three as *Beta alba*, *rubra*, and *nigra*. Some sixty years later naturalists made out nine species. These Linnaeus reduced again to two, besides the wild species—namely, *B. vulgaris* and *B. alba* or *cicla*. It will very likely remain an open question whether all the garden Beets are not variations, due to soil, climate, or culture, from *B. vulgaris*.

Amongst the ancients, so far as we can ascertain, only the leaves of the Beet were eaten, and means taken to induce the plants to form heads, resembling those of the Cabbage. Pliny, who gives some cultural instructions concerning the Beet, mentions the plan of putting a light weight upon the plants when they were colouring to promote the growth of the heads, but we may perhaps be allowed to doubt his story that in the territory of Circeii heads of Beet were produced which were 2 feet across. Some advised sowing the seed in spring and some in autumn. It was generally supposed to be beneficial to the young plants that they should be transplanted, and then well manured with a good supply of water if the weather was dry. Under the empire the Roman gentlemen only condescend to eat Beet when it was cooked up in spice and wine, because they deemed it so insipid by itself. The commoner class of citizens mixed with the leaves boiled lentils or mustard to give them a flavour.

Some have given 1548 as the year in which Beet was first raised by English gardeners, but about that date there is doubt; not much, however, in its being introduced by the Flemings, who brought over many plants, both flowers and vegetables, during the reign of Henry VIII. The author of the "Gardener's Labyrinth," one Thomas Hill, who devoted so much time to the planning of ingenious mazes and variegated mounds, mentions the Beet when writing upon plants in a volume published about 1595. At that period the Beet was evidently neither uncommon nor a favourite plant, for he refers to it in a way implying that those he addressed would have seen or grown it, and he adds that the plant was one

which was useful to poor men. If we were to attempt to fix the locality where Beet was cultivated near London in the days of the Tudors we should indicate the neighbourhood of Hoxton, or the not far distant Hackney. In both these districts many of the citizens had garden plots of different sizes, and grew vegetables for their own use, selling off a surplus occasionally to the City market women. South of London on the Surrey side we read of Tradescant cultivating Beet in moist Lambeth while Cromwell was Protector; Vauxhall and Battersea were also found suitable for it. The white Beet, however, did not reach Britain until late in the seventeenth century. Gerard, the worthy botanist and gardener, expresses himself in words more commendatory of the Beet than did Hill. "Red Beet boiled," says he, "and eaten with vinegar and pepper is a very delicate and excellent salad; but what might be made of the red and beautiful root I refer to the curious and cunning cook, who no doubt when he has had the view thereof, and is assured that it is wholesome, will make therefrom many divers dishes both fair and good." Until he threw out the hint the value of the root appears to have been scarcely thought of.

Evelyn soon after the arrival of the white Beet (which is stated to have been introduced from Portugal) took occasion to praise the leaves, or at least their midribs, which he thought to resemble marrow. To this hour the plant is largely grown in some continental countries in order that these, with their footstalks, may be cooked and eaten like Asparagus heads. Experiment has suggested other uses for the root beside; garnishing salads. Dried and ground they have been added to coffee, or mixed with a proportion of flour they have been made into bread. It has been asserted that the lassies of the north of Scotland use the juice of the Beet to impart a colour to their cheeks, which is cheaper than carmine or rouge; but this may be mere scandal, and most of them are rosy enough to need no such artificial adornments. An intoxicating liquor may also be made from Beet by fermentation.

The discovery that sugar existed in the Beet, more particularly in the white variety, is attributed to the Prussian chemist Margraff, who reported the fact to the Berlin Scientific Society in or about 1747. It was regarded as a matter of curiosity merely for many years, although Arhard, another chemist, tried to awaken interest concerning its possible uses; and he, with others, brought the subject before the Institute of Paris, but that august body, after sundry experiments, decided that there would be nothing gained by the attempt to extract sugar from Beet upon an extensive scale. A change was brought about by one of the features of the Napoleonic policy early in this century, when the Emperor, out of hostility to Britain, resolved to prohibit the importation of sugar from any British settlements, and the necessity arose for obtaining the article on French soil. At Rambouillet the first sugar factory was established; schools were also formed to instruct pupils, and since 1812 there has been a steady production of Beetroot sugar in France. Large manufactories exist in other countries of Europe, and the hint being taken by some of our fellow countrymen a factory was opened at Chelsea in 1837. Of late years special attention has been drawn to what might prove an advantageous industry to us in these times of close competition with foreigners, English-grown Beet having been found to yield 5 per cent. of sugar, which is good in appearance, though its sweetening power is less than that of cane sugar. Alcohol can be obtained from this sugar by the customary process.

The Mangold, now esteemed a valuable food for animals, received its German name, *mangel-wurzel*, which means "root of scarcity," by an error of spelling. It seems to have been first grown in Germany rather more than a century ago, and is probably a hybrid between the white and red Beet. Sir Richard Jebb had seeds of this variety sent him from Metz in 1786, and his distribution of these led the once famous Dr. Lettsom of Camberwell Grove to the writing of a small pamphlet upon the Mangold and its uses. The first crops of importance were raised in the county of Norfolk, near Burnham. By degrees the cultivation of this plant became general, and it has been a matter of competition to see how large a crop could be produced per acre, and what huge individual samples could be got; "mammoth" Mangolds, in fact, have been good rivals to the "big Gooseberry," of our newspapers.—J. R. S. C.

INSECT ENEMIES IN NEW ZEALAND.—The fourteenth annual report of the Botanic Garden Board of New Zealand (1883) contains valuable information as to the ravages of certain scale insects (*Coccidæ*) in the colony. They appear to be principally of two kinds: one is an *Icerya*, nearly related to the Sugarcane pest of Mauritius, &c., the other a *Mytilaspis* allied to the common "Apple scale" (*M. pomorum*). The *Icerya* is called the "Wattle blight," but appears by no means to confine

its ravages to the Wattle trees. According to Mr. Maskell it is the *Mytilaspis* that is the more serious, for it overruns in countless millions all kinds of fruit and other trees (fortunately it appears to be enormously infested and destroyed by a parasite). With regard to remedies, there is a little vagueness in the report, owing apparently to the confusion of the two insects. The first portion speaks only of the *Icerya*, and states that Mr. Engle of Nelson had completely destroyed it by the application of kerosene and fish oil. Subsequently Mr. Maskell, dealing with the two species, says that a mixture of kerosene and linseed oil (one-third or one-fourth of the former) as recommended by Mr. Comstock in America, had been perfectly successful so far as regards the *Mytilaspis*, which he does not regard as serious in its probable effect upon Wattles (*Acacia*), but very serious with respect to fruit and other trees. On the other hand, he considers all remedies useless against the *Icerya* of the Wattle other than the radical one of cutting down and destroying the affected trees. No indication is given, however, of the use of a force-pump in distributing the kerosene; if this were used, the remedial agent might be distributed to a greater height than would be possible by mere hand application, and, moreover, it might be made to penetrate dense hedges, &c., the interior of which it would be impossible to drench by hand labour. The same report speaks very hopefully of the ultimate success of attempts to cultivate Hops in the province of Wellington; in Nelson success has been already secured. The great drawback is the expense of providing the necessary poles, and much stress is laid upon the necessity for cultivating Oak, Ash, Birch, and species of *Eucalyptus* for that purpose. Of the indigenous poles, those of *Myrsine Urviliei* are said to be the most durable.—(*Nature*.)

VINES FAILING.

THE Vines which I replanted from those which had been hard frozen the previous winter (page 537, last vol.) began to move in July, new leaves formed, the leading buds plumped up fairly well, and there were some patches of a bluish metallic lustre in a few of the old jaundiced leaves. These patches were mostly on the strong ribs of the leaves, spreading a little on each side, but this is far from general amongst them yet. Roots, too, were moving; I examined a few, like the white end of a quill, only not so strong, but I did not detect any hairs on them. The two Vines which I put in by way of experiment had then scarcely started, except appearing a little more plumped. The new Vines were very healthy, the best about 5 feet long and the smallest 3 feet. These had been struck from eyes in the early spring of the same year, and had, as I suppose, received their last potting for the season; the roots were coming to the sides of the pots. Of course we could not spread out the roots in this case, so the balls were carefully placed in position with the addition of a little leaf soil and old mortar broken up as in the other case, a good soaking of tepid water given to each, and they were then kept in as warm and moist an atmosphere as could be given with safety to the Vines. With a hot July sun it was necessary to open the houses freely, and it was not therefore an easy matter to maintain a moist atmosphere in glass structures. By the first week in August all were growing fast, the foliage of a good dark colour, but the leaves first formed on the old replanted Vines were small and not so deeply coloured as the newer ones, less moisture was given and as much air night and day as possible, being careful to keep a good temperature. This state of things was continued until the first week in October, at which time several of the Vines had reached the top of the houses, but the wood was very green and soft. They were cut back freely, with the expectation of having one or two bunches from each Vine in the following season. The two Vines put in by way of experiment had not made much progress, and were cut back within two eyes of the border; also two of the others were cut lower down than the rest.

After giving the house a thorough clearing I examined the border carefully. This, as I expected, was dry, as my object had been to take care of the fibre, and had therefore only given sufficient water to keep the Vines healthy. Early in January we began to start the Vines. We had on some of the best Vines four bunches, three had only one bunch each, all the rest two or three each only. The two Vines which made very pithy wood did not show fruit, but it was difficult to restrain the growth, and with a dryish border as before the wood was well ripened by the middle of September; also the two which made pithy wood much improved, and the two planted by way of experiment had made very good canes. Pruning was then performed, following up with the same thorough cleaning as in the previous winter, only at an earlier date. In the first week of December we started the early house, but as we have insufficient pipes for winter work it was the first week in June before we commenced cutting Hamburgs. The Vines all ripened a most satisfactory crop, both bunch and berry being exceedingly fine. The two Vines planted by way of experiment have given one seven and the other five bunches of well-finished fruit; they chanced to be the Canon Hall Muscat. The soil of the borders is not much occupied by the roots, as I never thought of keeping them for permanent Vines. I have now another set of Vines between those first planted, which will be easy to keep to the surface now the border is settled, and we shall cut away the first-planted Vines as the new ones take their places.—R. LIVSEY, *Clairville, Birkdale, Southport*.

THE COCOA PLUM.—Those persons who visit Florida can, if they are interested in such matters, make the acquaintance of a number of wild fruits. Among these is the Cocoa Plum, of which some speak in high praise. The Cocoa Plum is *Chrysobalanus Icaco* (the generic name

meaning "golden acorn"); the genus is now placed in a sub-order of the Rose family, and differs from *Prunus*, the common Plum, in points only of interest to the botanist. It is a shrub from 6 feet to 12 feet high, producing white flowers. It is very common in all of the West India islands, and in Florida it is confined to the southern portion of the State. The fruit, in size and general appearance, is much like a common Plum, but is remarkably variable in colour, some being white, others yellow, while it is not rare to find specimens with red or purple fruit. The pulp is sweet, and, though a little austere at first, most persons become very fond of the fruit. In Jamaica and others of the West Indies, a conserve prepared from the pulp is an important article of domestic trade. The kernel yields an oil on expression. The leaves and roots are astringent and employed as local remedies.—(*American Agriculturist*.)

KITCHEN GARDEN.

Early Peas.—Where these are valued, and they are everywhere, their cultivation must now be commenced in earnest. Autumn-sown crops may be good in some places, and failure may be the result in others, but these must not be depended on altogether, as we have often had Peas appear strong, healthy, and well up in January, and yet they were very far from this after the February frosts and March winds were over, and those sown now or about this time came in before them. Young plants from autumn-sown seed should be as much exposed to air and sun as possible, and only give shelter from cutting winds. A good ridge of soil drawn up on each side is one of the best protectors they can have in spring, and little twigs are better to put on each side than tall bare stakes, to which the tendrils cannot readily cling.

There are many ways of raising young Peas in spring, but we only practise two of what we have proved to be the best modes. They are both simple. One is to sow the seed in the open ground, the other in pots. Round Pea seed such as William I. is very hardy. It will germinate now as well as in November or March, and a number of rows should be sown in the most sheltered corner available. Light rich soil is the best, and a quantity of sand put in with the seed is excellent for inducing quick and sure germination. If the seed be sown now the plants in ordinary winter weather would be 2 inches high a month hence, and will be sturdy in growth.

In raising Peas under glass there is no better way than sowing the seeds in 3-inch pots. Each pot should have a few leaves put in the bottom, then half fill with soil, putting about a dozen or fifteen seeds on this, and then fill with more soil. Two or three hundred pots filled in this way will give plants to make several rows, especially if each potful is turned out without breaking the ball and planted 4 inches or so apart. This is how we always treat them. As soon as the seeds are sown the pots are placed in a house, pit, or frame where the temperature is from 55° to 65°, and their germination soon takes place. As soon as the young leaves are visible the pots are kept near the glass, and air is admitted freely on all favourable occasions. As growth advances more ventilation is given, and by the time the Peas are 3 or 4 inches high they will have been transferred to a cold frame where they are thoroughly hardened, and then planted in the open ground in about one month from the time of sowing. In backward localities other batches may be sown in the same way to make two or three successional plantations before the end of March, when their culture in the open becomes an easy matter.

Kidney Beans.—These if sown like the Peas in small pots and grown on in 5° or 10° more heat will make rapid progress now. Osborn's Forcing is the best variety to sow under glass. Three or four dozen pots will form a good batch, and if this number are filled weekly until the end of March Beans may be gathered constantly from March onwards. Light rich soil suits them best, and as soon as the plants are 4 inches high they should be transferred to 7, 8, or 9-inch pots. Abundance of light, a genial heat, and plenty of water when growing fast will always bring Kidney Beans forward satisfactorily during the whole of the spring months.

Broad Beans.—Early Mazagan and Seville Longpod varieties should be sown at once. Stiff well-manured soil suits this crop. At present large quantities should not be sown, but only a few rows in an early position for a first crop. Our early Broad Beans are mostly grown between our Strawberry rows. As the ground is good and well exposed here, when the Beans are planted 1 foot or more apart they do not interfere with anything, but bear heavily.

Lettuce.—Early Paris Market and Wheeler's Tom Thumb should be sown now. At this time we only fill some of our cutting boxes of seed, which give 400 or 500 plants, and these make a good batch to begin the season with. Any kind of light soil does for starting the plants, and very little heat suffices to cause germination and make the plants grow; in fact, excepting during the time of frost any ordinary frame with a light over it is a suitable place in which to bring forward the young plants until they are large enough to handle, when they may be transplanted in boxes, frames, or sheltered places about the bottoms of hedges and walls.

Cauliflowers.—Some of the extra early sorts now offered by many seedsmen should be sown in the same manner as we have advised for the

Lettuces. Cauliflowers will bear a little more heat than these when young, but it is quite a mistake to employ great heat for any of them, as it only draws them up weakly. A pinch of Veitch's Autumn Giant variety and Webb's Mammoth, which is a splendid main crop variety, may also be sown to form a succession to the first. Cauliflower plants in frames should have the lights drawn off them whenever the weather is favourable, as dwarfness and hardiness are very desirable characters for them to possess in spring.

Carrots.—Sow Carters' Early Scarlet Marrow in frames. Light hot-beds will assist and forward them greatly, but where materials to form these are wanting put the frames on the ground and sow the seed within. Plenty of sand, leaf soil or half-decayed manure is useful to produce clean tender young Carrots.

Frame Potatoes.—These should now be planted largely, as quantities of young tubers will be much valued by Easter. Carter's First Crop and Sharpe's Victoria are two of the very best for planting at present.

Forcing Vegetables.—Continue to pot successional batches of Asparagus, Seakale, and Rhubarb in to force. They may all be brought forward easily now with less heat than two months ago, and the produce now is finer in quantity and quality. The floors of early vineries and under the stages of forcing pits may often be utilised for forcing at this time, and various kinds of salad plants, especially Mustard and Cress, may be grown in large quantities or inside Vine borders. Examine stored roots, and spread out early seed Potatoes that they may have plenty of light and air to make the young growths robust.

FRUIT FORCING.

PEACH HOUSES.—*Earliest Forced House.*—The trees in this structure being in full blossom impregnation should be attended to carefully. It is necessary that the pollen be ripe, and it is also essential that it be dry. The night temperature must be kept at 50°, or a little higher if the weather be mild, and allow a fall to 45° in severe weather. The day temperature may be 55° artificially, 60° to 65° from sun; above 55° commence ventilating. Leave the ventilators open a little at night, as nothing is so injurious to Peach blossoms as a close atmosphere. Damp the borders and floors occasionally. Disbudding should be deferred somewhat later in early forced trees than those coming on at a later date, yet it should be attended to as soon as the fruit has fairly begun swelling, and it should be done gradually. Leave a growth at the base of the present bearing wood to supplant it next season, and another on a level with or above the fruit to attract the sap to it, stopping it if not wanted for extension when a few leaves have been made. In young trees seek to secure main branches at 18 inches distance, and shoots along them for bearing at a similar distance. Whenever water is necessary, give it at the same temperature as the house.

House Started at the New Year.—The buds are swelling fast, and syringing must cease when the flowers expand, still maintaining a good moisture in the house by damping the floors and borders in the morning and early afternoon on fine days. See that the borders are thoroughly watered. Keep the night temperature 40° to 45°, day 50° by artificial means, ventilating from 50°, and allow an advance of a few degrees from sun heat, or 5° to 10° with free ventilation. If the blossoms are very crowded on the wood, rub off those at the under side or at the back of the trellis by drawing the hand the reverse way of the growth; this will strengthen those remaining considerably.

Succession Houses.—Whatever remains to be done in pruning, dressing the trees, and securing them to the trellis must be attended to without further delay, as the blossoms are swelling and will be in danger of dislocation. Ventilate fully, so as to retard the blossoms as much as possible.

Pines.—To insure a good supply of fruit in what is known as the London season give every encouragement to the Queen plants, and at this season, when the bulk of the plants are about starting, keep them well supplied with heat and moisture. The temperature should be maintained at 70° at night when the air is mild outdoors, and 5° less when the weather is cold; 70° to 75° by day, and 80° to 90° under sun heat. Close the house for the day at 85°, damp the plants lightly overhead about twice a week. Fruiting plants require similar treatment.

Succession Plants.—Keep the temperature at 60° at night and 65° to 70° in the daytime, and 80° from sun heat. As the time is approaching when potting must be attended to, see that provision is made of soil and other requisites.

Cucumbers.—The Cucumber house must have a night temperature of 65° to 70°, being guided as to the degree by the weather—75° by day and 85° to 90° with sun heat. Afford air on all mild occasions, and close early in the afternoon between one and two o'clock, or earlier if necessary, as sun heat is worth far more than fire, and sprinkle the house at the same time with tepid water. Examine the plants frequently for the removal of young fruits not required for succession, doing this shortly after setting. All male flowers should be removed, or only a few retained for fertilisation, so that when the successions have set they can be removed. A good bottom heat is of importance to insure a good supply of fruit, keeping it at 80° to 90°. Give thorough supplies of tepid liquid manure, but only when required. If the plants are weakly apply water only until they begin growing, and then encourage surface roots by top-dressing. Keep the seedling plants intended for the early spring supply of fruit well up to the light, top-dressing as they need it, or transferring to larger pots, placing a small stick to each when they need support.

PLANT HOUSES.

Soils.—These are of the greatest importance in the cultivation of plants, and it is necessary that they be in a proper state for use

when required. This can only be accomplished by keeping a good supply under cover during the winter and spring months. A large quantity will, in a very short time, be needed for potting, and everything should be done to forward that work rapidly. Loam and leaf soil, if left outside at this season until wanted, will be found in a very unfit state for potting purposes. A good supply of the former should not only be stacked inside, but if fibry broken up ready for use, removing all the worms. Cow and sheep manures, if properly prepared, are the best that can be employed for many plants. If this has been outside place it in some position where it can be gradually dried, until it can with ease be rubbed through a fine sieve. When it is in this condition it may be stored in any cool dry shed. Peat should also be broken up and all the soil shaken from amongst the fibre, the former for Orchids, and the latter will be invaluable for small Ferns and for filling pots in which cuttings that require peat will soon need to be inserted. A good stock of sand should be in readiness, with hones, quarter-inch, and meal, as well as charcoal, which should be broken in various sizes ready for use. Some coarse moss should also be in readiness for placing over the drainage; the refuse of the sphagnum required for Orchids, which must be picked in readiness, will be found useful for this purpose. In sorting this discard all the ends that have been nearest the ground and retain only that which is alive. The best heads should be selected for top-dressing, and placed in pans and watered freely until required for use. All empty pots must be washed; in fact, this should be done from day to day as they become empty, and never allowed to accumulate. The crocks to be used for drainage should also be thoroughly washed, then broken and kept in different sizes. This is readily accomplished by passing them through different sieves.

Cleaning Houses.—Before the season for potting arrives this work should be pushed forward. Houses that were washed in autumn should be done again. No plants should be repotted if they are infested with insects until they are thoroughly cleaned. If this work and the cleaning of houses are delayed until the potting is done, the plants are often seriously checked while the operation is going on, instead of receiving every encouragement to make luxuriant growth. The woodwork and glass should be thoroughly washed with soft soap and hot water, and if mealy bug has infested the house add one pint of paraffin to every four gallons of water used for this purpose, or paint the house with pure paraffin. The walls should be limewashed with hot lime, and if necessary add paraffin to this also. The pipes and staging, if ironwork, should be painted. Lamp black and boiled oil is very suitable for this purpose, but should be mixed very thin. The gravel or other material upon which the plants stand should also be washed or replaced with fresh. The stonework and paths, if flags, can be thoroughly cleaned by the application of a little chloride of lime.

Begonias.—Plants of *B. manicata* and *B. hydrocotylifolia* that have been up to the present time in a night temperature of about 55° should be placed in one 10° higher. Select those that have their flower stems most forward, for by the time they can be had in flower they will be wanted both in the stove and in the conservatory. In the latter place they are most useful, and last in bloom nearly twice the length of time that they will do in a higher temperature. These are two of the finest Begonias that can be grown for conservatory decoration. When used liberally amongst other plants they have a very light and pleasing appearance, and when in association with Epacris, and with a variety of dwarf flowering plants amongst them, it would be difficult to realise anything more striking or beautiful. After bringing them forward in the temperature indicated gradually harden them again to the conditions of a house 10° lower, and allow them to fully develop their flowers in the conservatory. By this means more highly coloured flowers are obtained, and they last longer than if fully developed in strong heat; and there is no fear of the flowers falling through being checked, which often is the case if removed to a temperature 10° or 15° lower all at once.

Cypripedium venustum.—When the old but useful *C. insigne* is past its best, as is the case here this season, the plants flowering a little earlier than usual, the above useful variety comes in and fills its place well. This variety has fine dark foliage, which, independent of its flowers, is very effective in the conservatory. The flowers individually are not so noble and striking as those of *C. insigne*, but good pans are very effective at the present time. It is very free flowering, and can be grown well under the same conditions as *C. insigne*; but we prefer to give it stove treatment, and keep the plants in a temperature of 60° during the winter, as by this means the plants will produce their flowers at a time when they are most wanted. If they are likely to come into flower too early the plants are retarded in a cooler place. They are never allowed to suffer from an insufficient supply of water at their roots while in the conservatory, and the lower temperature gives to them a short rest, by which they are much benefited.

THE FLOWER GARDEN AND PLEASURE GROUNDS.

Levelling Turf.—Where much work in the shape of levelling unequal lawns or the formation of tennis or cricket grounds is to be done, every advantage should be taken of dry mild weather, as it cannot be properly done during frosty weather. Novices in levelling are advised, where the ground is not particularly uneven, to first line and cut out the turf in strips about 10 inches wide and 1 yard lengths, these being thinly cut with a paring iron, rolled and stacked near where it will be again required. Then a number of pegs may be disposed over the ground about 4 feet apart each way, the first peg being fixed at the required height of the ground to be levelled, and from this peg the others can be adjusted, either with the help of a straight edge and spirit level, or with

three wooden sighting T pieces. The latter may be made with flat strips of deal, and ours are 3 feet in length and the cross pieces 15 inches. The tops of all the pegs will be level when the upper surface of the T pieces, if these are rested on them, are found to be in a line. It will then be a simple matter to either take away the soil or to add more where necessary, so as to bring all to the level of the pegs. It cannot well be made too firm; in fact, it must be rammed heavily or it will sink unequally. If the position is naturally wet, it ought to be drained previous to levelling, and heavy retentive soil should have a liberal quantity of ashes mixed with it, this tending to solidify the ground and better fit it for use during showery weather. After the pegs are drawn out a little fine good soil may be levelled over the surface, this giving the turf a good start. The latter should be laid closely and be heavily beaten down. If turf is scarce suitable mixtures of grass seeds may well be sown, but not till April, or much of it will be lost. We repeat that, to avoid subsequent unpleasantness or vexation, the greatest care must be taken to make a new ground quite solid, and great depths of fresh soil should be rammed according as the layers are added.

Hotbed for Propagating.—The seeds of several kinds of plants, notably tuberous-rooted Begonias, Lobelias, Grevillea robusta, Solanums and Cannas, Centaureas, Chamæpeuce, and Acacia lophantha, are best sown early, and they germinate the most readily when the pans and pots are plunged in a brisk and moist bottom heat. Tanners' bark is perhaps the most free of insect pests, but this heating material is not generally obtainable, and is only suitable for filling pits in forcing houses. Leaves give a good heat for a time, but are frequently full of troublesome white slugs, while stable manure alone is apt to heat too violently. If leaves and stable manure are mixed together in a large heap and turned in the course of about ten days, then allowed to ferment for yet another week, much of the rankness will have evaporated, and the slugs and their eggs probably destroyed. When with these materials a hotbed for a frame is made it ought to face the south, and be fully 4 feet high at the back and 3 feet high in front, and be beaten firm with the back of the fork. Six inches depth of cocoa-nut fibre refuse disposed over the surface of the bed, whether in a frame or forcing pit, is admirable for plunging in, and slugs do not travel over it freely.

THE BEE-KEEPER.

HOW I STARTED MY LIGURIAN STOCK.

AT the commencement of the past season I had made up my mind to try to place a Ligurian queen at the head of one of my hives. I had a vivid recollection of previous experiments when assisted by a far abler manipulator than myself. Then it was only on the third attempt that her Italian majesty was received, and it could not be said that afterwards the result was a success; on the contrary, as regarded Ligurians it ended in failure. Was this attempt to be any more successful? I selected a strong hive for the experiment, ordered my Ligurian, and caught and caged the English representative of royalty. In catching the latter she fell on the ground. I picked her up carefully; and used as I am to handling insects gently, I cannot believe that she was in any way injured. The queen cage was placed between two of the bars, and I awaited anxiously the arrival of Italian royalty. At the end of twenty-four hours I lifted the cage, and was astonished to see that the queen did not crawl up the cage. Waiting patiently for a few minutes without any signs of life, I pulled out the cage and found her majesty dead at the bottom. This was a blow to my hopes. I reasoned that if the bees would not care for their own queen when caged they would not be likely to notice in a proper spirit a stranger however grand her pedigree might be. In a day or two her majesty arrived, but on opening the box there were few signs of life—most of the workers dead, the rest dying; not one equal to flying, and the queen only moving slightly. I carried her to the fire, warmed her, tried to give her some honey, but after an anxious half-hour death put an end to my hopes. What was now to be done? The ordering another queen and the obtaining her took time, and meanwhile my stock to which I intended to introduce her Italian majesty had not been idle. Many queen cells were being built and completed, and seeing the bees were busily occupied with them, I decided to leave them to themselves and try another idea, which I hoped would insure me my Ligurian in safety.

Fortunately for my experiment the weather was hot. Taking then a large standard hive into a greenhouse I closed up the outlet, put in two or three bars of comb, and then obtained from one of my stocks a bar crammed with sealed brood. In order to further keep up the heat of the hive I kept a lamp under the floor board, a plate of tin preventing the heat being too great. Having then carefully put on the quilt over the bars, I placed the box containing the queen in the back part of the hive, opening it, but covering quilt and body of the hive with some netting, through which I could see what was going on. When thus at liberty her Italian majesty did not appear at all impressed with the responsibilities of her position, but flitted

about the hive, running over the combs, but rapidly leaving them, and as very few workers were sent with her I began to fear my experiment would by no means turn out a success. The portion of the hive she appeared most to enjoy was the portion on either side where there is a groove so that the finger and thumb can get down under the shoulder of the bar. Every time I peeped at her there she was with two or three attendants, and though blown at and made to quit her quarters she returned again. When not thus watching her the whole of the body of the hive was covered over by a thick horse rug. As the afternoon wore on without her appearing to take any greater notice of the combs my hopes went down to zero. Not so, however, the hive; thanks to the lamp being kept up under the floor board it was a comfortable warmth, and when as dusk advanced I took a last peep I was delighted to miss her majesty. On gently moving the quilt I saw a small bunch of bees on the brood comb, and covering all up and fastening in the dummy, I trimmed my lamp and hoped.

The hive was kept in the greenhouse for a couple of days, the entrance closed, and the warmth kept up night and day. Two days later I placed the hive outside and opened the entrance; they soon began to work; a fair lot of young black bees had hatched. A few days later I opened the hive, the queen was well and lively, laying abundantly; but many of the sealed brood had failed to hatch out, doubtless chilled. This comb, after brushing off the bees, I removed altogether for the melting pot; in its place I inserted another bar with sealed brood, these all hatched out, and as the Ligurians hatched the hive became fairly strong. This queen has proved a good breeder and the bees themselves most tractable. Later in the autumn the occupants of a condemned hive were added to them, and I trust next year they may increase rapidly and increase largely my stock of Ligurians. Thus far, then, my rather novel plan of starting a stock has been successful.—Y. B. A. Z.

SWARMING VERSUS NON-SWARMING.

THE above has occupied my attention for a number of years, and as yet my opinions are not at all settled on the point. Some writers tell us that it gives them little or no trouble to prevent swarming, and consequently obtain large harvests of honey. Others equally as eminent in bee-keeping have told us in their writings that they have experienced considerable difficulty in keeping bees on the non-swarming system. Mr. William Raitt has discussed the subject in these pages very ably, and has said that, taking all things into consideration, he believes in a moderate increase of stocks, which would mean about one swarm off each stock. For my part I think this reasonable and practicable, and would be a really good plan where a very long season could be had, to finish up with the Heather; but here (Co. Down) we have a very short season, as the glut is only from about the middle of June till the middle of July. I say "glut," as the bees get honey here from the time the Crocuses appear until frost sets in, but not in sufficient quantities to enable them to store much, it being all consumed in raising brood.

Swarms here are generally late, especially in bar-frame hives that have been supered as soon as the colony became crowded in the brood chamber; but even in hives that have not been supered it is generally well on in June before they would swarm. With the Clover so near I consider it a misfortune to have to make two swarms of my strong one, and to prevent it I put on a tray of sections, and all goes on well for a few days; but when the sections are nearly built out and well crammed with bees, off goes the swarm and not a bee is left in the sections. I decide to put them back, so the tray is removed and each frame, all the queen cells are cut away, the frames are re-arranged, and the tray of sections placed on the top. The swarm is then returned to its old home, but in a few days the bees depart again; and since the last time they swarmed they were very idle, comparatively speaking, for I find they never work so well after they swarm and put back again—they "sulk," as it were.

My objections to the swarming system in the north of Ireland, and, indeed, in very many parts of the United Kingdom where the honey glut is of short duration, are that swarms can only be obtained late or on the eve of the glut, and when obtained are not able in so short a time to fill the body box and enter supers in time to fill them. A mistake one of my queens made last season suggested a thought to me I will give to your readers for full discussion, and I believe this would be a good time of the year to have this discussed, as we could all start with our minds made up what we were going to do with our hives this summer. I, for one, shall be most thankful for the opinions of others on this most important point in the management of bees. The above-mentioned queen entered the wrong box when attempting to return to her own hive after swarming, and was killed. I gave to her stock hive a virgin queen I had in reserve and all the swarm hatched again. This, of course, put an end to swarming in this hive. Now, it struck me that if we could not prevent swarming, and our bees would swarm in spite of us, to secure the swarm, catch the queen and keep her from the bees, cut out all the queen cells but one, and then return the swarm. Having lost the old queen, and having the full stock of bees with a virgin queen, they would work with at least their usual vigour, and swarming would very likely be stopped. What do others say?—COMBER, Co. Down.

TRADE CATALOGUES RECEIVED.

J. Cheal & Sons, Lowfield Nurseries, Crawley, Sussex.—*Catalogue of Vegetable and Flower Seeds.*

Kelway & Son, Langport, Somerset.—*Manual for 1884.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (Eldred B.).—Buchan's "Introductory Text Book of Meteorology," published by W. Blackwood & Sons, price 4s. 6d., will give you full particulars on the subject of barometers. (J. E.).—Shaw's "London Market Gardens," published at 37, Southampton Street, price about 3s. or 4s., is the best we know on the subject. (James Wood).—There is no large work corresponding to the volume you name. Our "Garden Manual," price 1s. 6d. post free, gives sound and concise information on the culture of hardy fruits and Vines under glass.

Propagating Gynura aurantiaca (F. C.).—This plant is readily increased by cuttings of the shoots inserted in sandy soil and treated like Coleuses. It requires a temperature of about 60°, and the plants should be grown in the stove or intermediate house during winter. In spring and summer they may be treated like other bedding plants, gradually hardened off, and placed out in beds as a margin. The old plants may be lifted in the autumn and potted.

Culture of the Edelweiss (E. T. H.).—The seeds may be sown in sandy soil in spring, either in a sheltered position outside or in pans in a cool frame or house. The plants will require a rather rich, but not rank, and moderately moist soil, but the position must be thoroughly drained, or failure will be the inevitable result. On a rockery it is seen to best advantage, and when thriving it has a very pretty appearance. The plants can be divided each year if desired.

Apple Trees Cankered (J. Hirm).—The example sent is seriously cankered; and as it appears that many trees are similarly affected, we have no hesitation in attributing the cause mainly to the severity of the winters of two or three years ago, notably during the winter of 1880-1881, and the previous immature state of the wood. The subject will, perhaps, be further alluded to.

Calceolarias (A. S.).—Every gardener is liable to accidents, and few escape them in some form or other. You have, however, no cause for alarm that you will have "no Calceolarias worth looking at," provided you grow the small plants, now 3 or 4 inches in diameter, well, allowing them to receive no check whatever either from neglect in watering or too dry an atmosphere, attacks of insects or excessive fumigation. They can be placed on damp ashes in a pit, from which frost can be excluded; and with good and generous culture you ought to have handsome plants by the end of May.

Dressing Vine Borders (A Lady).—The benefit derived from dressing the borders with guano and other fertilisers depends far more on the state of the roots of the Vines than on the manurial value of the dressing. Many borders, especially where the Vines are old, contain practically no feeding roots, these having extended far beyond the borders, even if these are inside the house. In such a case the best course to pursue is to remove the soil from the roots, cut notches in these at intervals of 2 or 3 feet by first cutting straight down almost to the pith, then slanting upwards to the stem of the Vine, covering these with a gritty mixture of loam, leaf soil, and wood ashes, over this placing 4 inches of good loam, and then a surfacing of rich manure. The border being kept moist fresh roots will soon be plentiful; then, and not till then, fertilisers can be applied with

great advantage. Assuming that your Vine border contains abundance of small fibrous roots near the surface, and the Vines need more support than the soil affords, you may spread the manure on the surface at the rate of 2 ozs. per square yard about the flowering period, and again after the Grapes are freely swelling after having been thinned, on each occasion watering heavily to wash in the virtues of the dressing. Just as colouring commences a further dressing may be given if needed.

Stopping Tomatoes (Idem).—Usually when Tomatoes are well grown under favourable conditions flower trusses issue from the main stem, and if these are fertilised and fruit follows, the side shoots that are produced on the same stem should be rubbed off entirely, not pinched to one joint; but if flower trusses are not produced, then the plant should be topped, and the laterals that follow will be almost certain to produce them; one of these may be stopped close to the truss and the other taken up as a leader. In all probability this will produce flower trusses at every joint, and if the pollen is dry the fruit will set, the side growths may then be taken off as before and the stem will only be clothed with the large main leaves and fruit. Rubbing the hand lightly over the trusses when they are quite dry about midday, or shaking them, will aid in distributing the pollen and the setting of the fruit. One stem trained up each side of the pillar will suffice; but if your Tomatoes are under the shade of Vines it is probable you will have to adopt the stopping method occasionally, as the main stem will not be short-jointed, nor produce sufficient trusses for developing a satisfactory crop of fruit. We shall be very glad to aid you at any time in rendering your garden enjoyable. We do not think the variety General Garfield will afford you the utmost satisfaction; it is large but very coarse.

The Mangosteen (Under Gardener).—You are quite right, the Mangosteen is considered the richest and most wholesome food in the world, and is produced by *Garcinia mangostana*. The tree is about 20 feet high, with flowers like those of a single Rose, and leaves 7 or 8 inches long, of a shining green colour above, and olive-green beneath. The fruit is of the size and shape of an ordinary middle-sized Orange, green at first, but as it ripens becoming of a dark brown colour, with yellow or grey spots on its surface. The rind is about a quarter of an inch thick, somewhat like that of the Pomegranate, but more succulent; of a rose colour inside, and with a purple juice and an astringent taste. The pulp is divided into segments like that of the Orange, but unequal in size, and not adhering to each other. The flesh is of a most delicious flavour, resembling a mixture of Grapes and Strawberries, and abounding in juice, which has a fine admixture of the sweet and the acid. "When eaten," says Thunberg, "the rind is generally pared off all round, and the pulp, which is white, soft, sweet, and inexpressibly delicious, is put whole into the mouth, in which it melts like whipped cream. It has a most pleasing mixture of acid, with a small degree of sweetness in it, which does not incommode the stomach, neither is one easily satiated with it." Each segment of the fruit contains a seed like an Almond kernel. Any quantity of the fruit may be eaten without inconvenience, and may be given without scruple to the sick, who, when they have no relish for any other food, eat this with great delight; but should they refuse it, their recovery is no longer expected. Dr. Solander, when in the last stage of a putrid fever at Batavia, found himself insensibly recovering by sucking this delicious and refreshing fruit. The dried bark is used with success in dysentery and tencismus, and an infusion of it is esteemed a good gargle for a sore mouth or ulcers in the throat. The Chinese dyers use the bark as a mordant to fix a black colour. The Mangosteen is a native of the Molucca Islands, and is cultivated in Java and several other islands of the Eastern Archipelago.

The Best Grapes for January (L. L. B.).—Opinions differ, as you appear to have ascertained, as to the two best Grapes, one black and one white, for high-class dessert purposes in January. Tastes differ, and so do circumstances. The same varieties of Grapes do not succeed equally well with all persons. We perceive you have not found much difference of opinion on the question of white Grapes, as the majority of persons would have no hesitation in according the palm to the Muscat of Alexandria. It will be on the question of black Grapes, we imagine, that you have had conflicting replies. Probably several prefer the Alicante because of its appearance, but it is seldom sufficiently high in quality for a "high class" dessert; others no doubt have named Gros Colman for the same reason, and it is sometimes good, while Lady Downe's has its admirers. Gardeners who have the Black Hamburgh fresh and good will say "none beats it," but the majority of growers cannot rely on having it in good condition at this season. Then, a few may possibly name Mrs. Pince's Muscat, and those who have it in first-class condition have good reason to esteem it, for well coloured and ripened we doubt if there is a finer and better black Grape in use at the present time. You will thus perceive it is not easy to give a "plain reply to a plain question" as to which is the best black Grape for January. Our readers are quite at liberty to express their opinions on this point, and you might, perhaps, express yours, as you appear to have given considerable attention to the matter.

Gloria Mundi Apple (J. Mapleson).—You ask first "if we really consider this variety and Belle Dubois synonymous?" Our reply is in the affirmative. Next, as if anticipating our verdict, you inquire "whether 'the Apple' was raised in England or France?" as this, you think, would settle the question as to priority of names. Such questions are not so easily settled as you appear to imagine. In the first place the Apple was not raised in either of the countries named. It is of American origin, but some doubts exist as to where it was first raised, that honour being claimed by several different localities. The general opinion, however, is that it originated in the garden of a Mr. Smith, in the neighbourhood of Baltimore, and was brought over to this country by Captain George Hudson, of the ship *Belvedere*, of Baltimore, in 1817. It was introduced from America into France by Comte Lelieur in 1804. But from the account given in the "Allgemeines Teutches Gartenmagazin," it is doubtful whether it is a native of America, for in the volume of that work for 1805 it is said to have been raised by Herr Künstgarner Maszman, of Hanover. If that account is correct, its existence in America is, in all probability, owing to its having been taken thither by some Hanoverian emigrants.

Difficulties of a New Garden (M. Farmer).—Burnt clay would improve your stiff soil, but it is not to be regarded as indispensable. Coal ashes are much better; and a few heavy annual dressings effect such a thorough mechanical division of the soil as to render it permanently light and porous.

Divide the kitchen garden into quarters by two central paths intersecting each other at the middle of the garden, also make a path round the garden 6 or 8 feet inside the boundary; 4 feet is an ample width for the paths of so small a garden. This method of division gives facility of access to every part; it also gives four large square plots for the main vegetable crops, and borders for Strawberries, salading, herbs, and many other vegetables of which small quantities in succession are required. Fruit trees, whether espaliers or pyramids, should be planted alongside the paths, so as to encroach as little as possible upon the squares or borders. Shelter from the north and east is required in winter and early spring when deciduous trees are bare of leaves. Evergreen Firs must, therefore, be used either mixed of common Spruce, Scotch, Silver (*Picea peetinata*), or Austrian Pine, or separately. If the position is much exposed plant several rows, so as eventually to have a dense mass of foliage, the permanent trees to be 12 feet apart, with Larches between 3 feet apart. The Larches are gradually removed as the branches of the other trees spread, and afford a supply of stakes that is useful for garden purposes for several years. Keep the front row of this sheltering belt full 30 feet from the garden boundaries, so as to avoid risk of the roots encroaching upon the crops. In connection with shelter do not forget that a wall is not only valuable, but that trees trained against it very frequently have fruit in abundance when those out in the open garden have none at all.

Select Hardy Plants and Shrubs (*Idem*).—If you will make your query as to what flowers you shall plant somewhat more definite we shall then be able to assist you. Your expressed desire for "herbaceous borders" shows that you care for such plants, so we name a few, but there are numerous others worthy of a place:—*Acanthus latifolius*, *A. mollis*, *A. spinosus*, *Achillea Ptarmica flore-pleno*, *Scabiosa coccinea*, *Allium pedemontanum*, *Anemone japonica*, *A. japonica alba*, *Spiraea palmata*, *S. japonica*, *S. filipendula flore-pleno*, *Aquilegia glandulosa*, *A. chrysantha*, *Bocconia cordata*, *Carnations*, *Picotees*, *Pinks*, *Pyrethrums*, *Pentstemons*, *Delphiniums*, *Irises*, *Phloxes*, *Pæonies*, *Polygonums*, *Potentillas*, *Dictamnus Fraxinella*, *Monarda*, *Dielytra spectabilis*, *Meconopsis nepalense*, *Papaver orientale*, *Plumbago*, *Larperetæ*, *Tradescantia virginica*, *Zauschneria californica*, with all the old familiar varieties of bulbs intermingled, with space between for the best annuals, such as *Asters*, *Larkspur*, *Stocks*, *Mignonette*, *Zinnias*, *Candytuft*, *Phlox Drummondii*, *Petunias*, *Godetias*, and *Balsams*. Of evergreen climbers for your house take *Escallonia macrantha*, *Ceanothus rigidus*, *Berberidopsis corallina*, *Akebia quinata*, *Garrya elliptica*, *Cotoneaster microphylla*, *C. Simmondsii*, *Elæagnus pungens variegata*; and of deciduous sorts *Ampelopsis Veitchii*, *Lonicera flexuosa*, *L. brachypoda*, *Clematis montana*, *C. flammula*, *C. Jackmanii*, *C. The Queen*, *C. coccinea*, *Wistaria sinensis*, *Jasminum officinale*, *J. nudiflorum*, and *Solanum jasminoides*; and in planting mix evergreen with deciduous, so that the growth may blend and the walls never become bare. Give your gardener £65 a year, with cottage, fuel, vegetables, and milk to begin with, and if he proves a really valuable servant add to his wages subsequently, for be assured that liberality then will be to your mutual advantage.

Mushroom Spawn (*J. E., Essex*).—Your questions are exactly similar to some received from a correspondent some time ago, and answered as follows:—*Milltrack Mushroom spawn* is that which is found in the accumulated manure of horse or cow stables. It used to be plentiful in the tracks of horses that were employed in working mills and threshing machines in the olden time, hence its name. It is almost impossible to teach anyone to make Mushroom spawn bricks except by example, and it is not unlikely you will err if you attempt to make a "large quantity." Try a small quantity first. The following is the plan described in the "Cottage Gardeners' Dictionary," and is good when properly carried out:—"Take three parts of horse dung without litter, two of cow dung, one of decayed tanner's bark, and one of sheep's dung, and one of good loam; mix to the consistency of mortar, and mould in small frames like those used by brick-makers, 6 inches long, 4 broad, and 2 deep. Three holes to be made half through the bricks, an inch apart, with a blunt dibble for the reception of the spawn. They should be put on boards for the convenience of moving abroad during fine days, as they must be made perfectly dry, which they often appear to be on the outside when they are far otherwise internally. Before they are perfectly dry they require great care in handling and turning, from their aptitude to break; but in about three weeks, if dry weather, when perfectly dried, they become quite firm. To pervade them with the spawn, a layer of fresh horse litter, which has laid in a heap to sweeten, as for a hotbed, must be formed, 6 inches thick, in a dry shed. On this a course of the bricks is to be laid, and their holes completely filled with spawn; and, as the bricks are laid in rows upon each other, the upper side of each is to be scattered over with some of the same. The bricks are not placed so as to touch, so that the heat and steam of the dung may circulate equally and freely. The heap is to terminate with a single brick, and when completed covered with a layer 6 inches thick of hot dung, to be reinforced with an additional 3 inches after a lapse of two weeks. The spawn will generally have thoroughly run through the bricks after another fortnight. If, however, upon examination this is not found to be the case, they must remain for ten days longer. The bricks being allowed to dry for a few days before they are stored, will then keep for many years."

Names of Plants (*W. E.*).—We have frequently stated that we do not undertake to name florists' flowers, as it is almost impossible to determine them without comparing them with a large collection.

COVENT GARDEN MARKET.—JANUARY 16TH.

No alteration with the exception of Grapes and Cucumbers, both of which are in good demand at improved prices.

FRUIT.

NEW AND IMPROVED AGRICULTURAL MACHINERY.

(Continued from page 34.)

CORN and seed-dressing machines were a large and important part of the late Show at Islington Hall. The cellular class of rotary corn and seed-separators were more numerous than on any former occasion. At a former meeting of the Royal one of these, a French-made machine, was shown, and shortly after an improvement was patented and shown by Mr. Charles Dellar of Melbourne, Cambs. This year Mr. Dellar has exhibited an improved machine patented by him, the cup cells on the inner periphery of the cylinder being arranged diagonally. The cells can be made of any size, and the cylinders of any diameter and length. They are a practical success, and are in extensive demand for use by corn merchants and millers in cleaning home-grown corn as well as imported Wheat, Barley, and Oats, also by the farmer for separating seeds from his Wheat. At the same time they are recommended for the separation of Oats from Barley, as it is notorious that the best grain for malting purposes is frequently found in the samples of drege. We know one corn merchant who is a large buyer of drege, and makes it answer his purpose well to separate the Barley, &c., from samples of mixed corn. It can also be used for separating the grain when Beans and Peas or Beans and Vetches are grown together, and as this practice is becoming more general by Bean cultivators on strong soils it is of increasing importance. Corn and seed-drying machines can be made upon the same principle, and would not only prove better but cheaper than are Gibbs' drying machines; and to this we call the attention of Mr. W. Gibbs and other makers of corn-drying machines, the cell principle adopted being decidedly superior to any other plans yet discovered. Messrs. Burlingham, Innes & Co. of the Exchange Works, Hitchin, also exhibited a screen for the same purposes of separating corn from weeds, for which the power required in working is very small compared with some other machines. At the same time where large quantities are required to be dealt with two or more of these cylinders can be combined to work in one frame.

Messrs. R. A. Lister & Co. of the Victoria Ironworks, Dursley, Gloucestershire, exhibited a new and improved mill that will meet a long-felt want, and is capable of cracking or crushing from eighteen to twenty bushels of corn per hour, or grinding from six to eight bushels into meal of the finest condition adapted for pig or cattle-feeding. It can be driven by a small three-horse-power engine, and is so simple in construction that any ordinary labourer can manage it. Under our present system of feeding our horses, cattle, sheep, and pigs, it is of far greater importance than at any former period. The home farmer now never thinks of feeding his horses with whole corn of any kind, as he knows that crushing is of vast importance in feeding, but more particularly where some of the animals are aged and having often defective teeth. When crushed, however, meal should be mixed with pulped roots or damp chaff of hay to prevent waste. But in feeding our fattening cattle or dairy cows it is best to give all artificial or corn foods in the meal state and in admixture with cut or pulped roots. Again, with sheep feeding both cake and corn should be reduced to meal and mixed with cut roots in order to prevent waste. Pigs also at the early stages of feeding should get meal mixed with pulped roots, varying in proportion to their fatness.

Messrs. Vipan & Headley, of Church Gate, Leicester, showed a number of dairy appliances, and it is said that their newest railway milk-churn cannot be improved upon, as it is most substantial, being made of steel in one plate, with only one seam, and coated with tin.

The top of the churn is so arranged that any dust or dirt accumulated during transit does not fall into the milk when the lid is hurriedly taken off or washed by rain. The arrangement of the lid is such that any milk displaced during transit is thrown back into the churn, instead of washing up the sides of the lid and ventilator. The fastening can either be used with or without a lock. The bottom of the churn is stamped by machinery and driven into position, rendering it nearly impossible for the rim or hoop to be knocked off. The fastenings are out of the way and cannot be injured when churns are placed on each other; neither are there any projections to knock off when the can is tilted to drain. The handle is rivetted to an independent plate and soldered on the can.

Messrs. Barnard, Lake & Co., of Rayne Foundry, Ipswich, have added further improvements to the patent thatch-making machine invented by Mr. Gooday for stitching straw, for covering corn and haystacks, root heaps, sheep folds. This is really of consequence in use, now it is customary to make hay and corn ricks in the field, which are often seriously damaged by rain before the professional thatcher can do the work of drawing and laying on the thatch in the usual way. Stackcloths can be dispensed with. The saving by using machine-made thatch is that it saves straw, time of yealming, and fetching of water, considerations of importance in the hill districts. It is quite proof against rain after a dry time, being made so firm in a dry state that it never becomes loose. Can be made and stored away in winter in readiness for the busy periods of haying and harvest. An improvement is noted this year, the string or yarn used for binding being not only cheaper but stronger. Comparisons, however, may be made by the home farmer between this thatching as against corrugated iron, which is now often used, being made in plates, is easily put on and will last for years.

Mr. Wm. Wade, of Hunslet Lane, Leeds, manufactures a barrel churn, of which the important advantages are that it produces butter in a remarkably short time, it has a discharge valve and a catch to hold the churn firm while the cream is being poured into it and also while the butter is taken out. It is equally adapted for churning milk as well as cream; the axles being fixed at the sides give the churn an end-over-end motion. The advantages of which are, not having any beaters or dashers in the inside it is very easy to keep clean; the butter can be taken out without being touched by the hand; the opening into the churn is at the end, on which is secured the loose lid, which is easy to fix or take off, and being made air-tight there is no waste of cream; it produces the butter in the globular form. We must close our subject for the present by the notice of Fairbanks' platform weighing machine, which has lately undergone various improvements, and has wrought a revolution in almost every department of business where the measurement of quantities is required relating to heavy bodies of every kind connected with the commerce of the country, and are specially useful in farm practice, for not only can live cattle be weighed, but also every item great or small being the produce of the land. This machine is sold by Messrs. E. & T. Fairbanks & Co., of Upper Thames Street, London.

WORK ON THE HOME FARM.

Horse Labour.—In all those cases where from necessity the seed time or Wheat has been delayed, it may now be done with a fair prospect, for if the seed can be buried and the land worked off into proper shape and form on the surface, for the heavier the land is the better in January or February, simply on account of the same opportunity as to condition and state of the land is afforded to the young Wheat plant as in the autumn seed time, and which delights in a close moist state of the land. But when in January and February the soil happens to be dry, should the land work off ever so fine it is not kind for Wheat, and would favour a large growth of weeds of whatever kind may be indigenous to the soil. We therefore recommend when the ground is not in a promising state for the production of Wheat as above stated, that it should be held over and prepared for Lent corn, taking Oats or drege on the strong land, and Barley on the light, dry, and friable soils. The weather has not been favourable for threshing corn ricks, but every opportunity should be taken, as this work, involving some horse labour, we designate as part of the winter work for horses on the farm. If the corn is not sold it may be stored in the granary, but it must be an unknown verse in the chapter of accidents which will make any important rise in the price of corn. At present we are carting and laying-out chalk, and we obtain this article in as fine state as possible, otherwise much hand labour is required to reduce large lumps into a beneficial and workable state. We having grubbed-up hedges and drained the ditches on part of our farm, it is convenient to lay out the chalk upon the land thus gained as it is cast from the waggons and carts. Some horses are now engaged in work connected with orchard-planting, especially of the best sorts of Apples, Filberts, Cobnuts, Plums, Damson bushes, also bush fruit generally, such as Gooseberry and Black Currant. Carting and laying-out farmyard dung on to the Clovers wherever the land will bear the carts should be done, and also carting earth as composts for pasture and park lands. At the same time earth should be stored and kept dry until it is required for the bottoms and floors of cart-horse stables, also all cattle pens, as well as pig pens, for it is notorious that the loss by drainage from farmyards is tremendous. Where open and under ordinary

management we never used and converted annually less than 150 cart-loads of earth every year, after having been thoroughly saturated with urine from all the tables and pens on the farm.

Hand Labour.—In the Hop-growing districts much care and thought should now be used in providing Hop-poles, and these may be obtained from various places on the estate if attention be given to it, as a necessary item for growth in connection with Hop gardens, now where there are wide rows between the fields. Hop-poles can be obtained by reserving the wood until the stems are of sufficient strength and length. Maple, Ash, and Oak are adapted for this purpose. In the woodlands also it is the same, except that where these underwoods are absent the land may well be made out by the planting of Sweet Chestnut plants, which will come to hand very quickly and answer a good purpose. Hedging, ditching, and banking will still be going on where required. also the planting of Thorns for fencing should be done. Men will be spreading dung on the Clovers, chalk on the fallows, also assisting in the work of orchard-planting. It is quite an undecided point with many as to what should be grown in young orchards. It is even a question with some as to whether grasses should be laid down or crops like Potatoes, &c., grown, also Mangolds and Cabbage. This will, of course, depend upon the soil. When the soil is poor it should be trenched before planting, and where the land is rich and deep it may not be trenched, but only carefully planted, and when the land is seeded down in this way too luxuriant growth of the trees is avoided, and the bearing wood only is encouraged.

Live Stock.—The lambing folds for both Down and long-woolled ewes will have been made or are making. In the districts where Hampshire Downs are kept as a breeding flock lambing is now going on, and those districts where the long-woolled breeds are reared lambing will soon commence. When either ewes or lambs fail in health it should be carefully observed by the shepherd which requires treatment and extra attention. It may, however, be both ewe and lamb, for in some cases when ewes have an overflow of milk the lamb cannot take it all; hence an accumulation of milk, which coagulates in the udder and injures the young lambs. It is imperative that the milk should be drawn away daily until the lambs can keep pace with the supply of milk. When neglected it is a fruitful source of injury, frequently applying to both ewe and lamb. When young lambs prove unhealthy two complaints particularly prevail—namely, the "white scour" and "rheumatic affections." The first is frequently beyond control, but we find the best remedy is ten drops of tincture of opium and a little prepared chalk in a half wineglass of warm water. This is for a lamb at any age under one month, and should be given every three or four hours until cured. The rheumatic complaint affects the use of one or more legs, and the animal becomes crippled and cannot follow its dam. This disease, unlike the first-named, has no remedy. The lamb should be destroyed and replaced by another, taking care to first draw away any accumulation of milk from the udder, as coagulated milk is the most fruitful source of disease amongst young lambs.

OUR LETTER BOX.

Alderney Cow (Inquirer).—We should not choose North Wales for any of the Channel Island cattle, but the Guernseys are the most hardy and the best suited for a cold hill district; still in vales and sheltered positions Alderney and Jersey cattle may do with careful management. From the second week in May until the 1st of October they may feed on grass in the pastures night and day, but afterwards they should lie in their pens at night and receive a full allowance of good hay, bran and Potatoes, Cabbages, Carrots, or Mangolds, with what grass they can obtain in the daytime. This food will enable the cows to yield plenty of milk and cream for butter. If they calve in the early autumn it is, however, best not to have them in full milk during the winter. They will then, if dry, only require hay and any grass they can pick up on the pastures. For management all the year through we advise you to obtain from the office of this Journal the number dated May 19th, 1881, containing full particulars of management of the Channel Island cows all the year through.

REMARKS.

6th.—Fine and dry, with sunshine at intervals.
7th.—Beautiful sunrise; bright clear morning; overcast afternoon; sharp shower 5.25 P.M.; rain in evening.
8th.—Fair at first, afterwards wet and dreary; moonlight night.
9th.—Fine pleasant day, but not very bright.
10th.—Fine, with bright sunshine; lunar halo all the evening; bright moonlight night.
11th.—Fine generally; heavy shower at 1.30 P.M.; bright moonlight night.
12th.—Fine bright day, and colder; beautiful sunrise and sunset.
A much brighter week; temperature, especially at night, much above the average.—
G. J. SYMONS.

29	TU	
30	W	Society of Arts at 8 P.M.

HYBRIDISING POTATOES.

A NEW phase of that highly important subject, the production of disease-resisting Potatoes, has been opened by Mr. Baker of Kew, who, at the last meeting of the Linnean Society, gave the outline of a series of exhaustive researches and observations respecting the tuber-bearing species of *Solanum*. His investigations were undertaken at the request of Lord Cathcart, and the object was to determine the number of really distinct tuberous *Solanums*, their distribution, and the characters of the climates to which they are peculiar. To effect this satisfactorily it was found necessary not only to carefully compare a very large number of specimens from the various districts of North and South America with the descriptions given by botanists who have reviewed the genus, but also to determine the range of variation in the Potatoes cultivated in English gardens. The latter portion of the task was undertaken last autumn, and the varieties grown in the grounds of the principal seedsmen were fully examined and classified, one result being that Mr. Baker considers it incontestably proved that all are descended from the true *Solanum tuberosum*, and that no other species has played any part in the production of cultivated Potatoes.

This point being settled, it became necessary to determine how many of the tuberous *Solanums* described in botanical works merit the rank of species, and the conclusions arrived at under this head were that the majority of those mentioned in Decandolle's "Prodromus" and other works are simply varieties of *S. tuberosum*, and that, including this, only six well-marked species can be named—*i.e.*, *S. Maglia*, *S. Commersoni*, *S. cardiophyllum*, *S. oxycarpum*, and *S. Jamesi*. These extend in geographical range from Chili to New Mexico and the Rocky Mountains, and consequently inhabit climates varying greatly in temperature and humidity, both of which have an important bearing upon the adaptation of the progeny of such species to cultivation in the British Islands. In Chili is found the true *S. tuberosum*, which grows wild at great elevations in the Andes, where at least for a great portion of the year the climate is exceedingly dry, and therefore differing considerably from the average English climate.

In the lower portions of the district, in the valleys, and as the coast is approached, the humidity is greatly increased until the rainfall is very high and the vegetation correspondingly luxuriant. There is found the *S. Maglia* of Baker, which he considers easily separable from *S. tuberosum* by characters of the foliage, flowers, and fruit, which need not be detailed here. It produces tubers of moderate size, 2 to 3 inches long, somewhat kidney-shaped, solid, and when cooked of fair flavour, evidently possessing a large quantity of starch. This has been grown at Kew for nearly twenty years, but has been generally regarded as the true *S. tuberosum*. It is perfectly hardy, the roots being left out unprotected, is very strong in habit, with broad leaflets, and it has not been attacked by disease, the produce being abundant

and regular. Sixty years ago a coloured plate and description of the so-called wild *S. tuberosum* was given in vol. v. of the London Horticultural Society's Transactions, together with a full description and results of its culture in the Society's gardens, by the then Secretary, Mr. Joseph Sabine. This Mr. Baker considers to be really *S. Maglia*, and as the results there given are very favourable, he regards it as good evidence of what careful cultivation might effect. In "A Naturalist's Voyage Round the World" Darwin referred to the wild *S. tuberosum* as being found in damp forests of the lower parts of Chili and in the neighbourhood of Valparaiso, and comments upon the remarkable range of climate the plant endures, from the arid regions of the Andes to the humid districts in the lower parts. Here again Mr. Baker regards *S. Maglia* as the subject of Darwin's observations, and not *S. tuberosum* as was supposed; and many other facts were adduced to prove that the two species had been confounded by travellers and botanists.

A third species, *S. Commersoni*, is found in Brazil, and is very distinct from the two former, being of slender habit, with small leaflets and deeply cleft corollas. This has been recently introduced to the Continent under the name of *S. Ohroni*, but has never been cultivated in England. It has small tubers, said to be of good quality when cooked, but less is known respecting it than of *S. Maglia*, though probably more will be heard of its characters during the coming season. Many forms are found in Brazil, but they are all referred to this species.

Mexico claims three species—*viz.*, *S. cardiophyllum*, *S. oxycarpum*, and *S. Jamesi*; but the only one of these that appears likely to prove of horticultural importance is the last-named, which has been grown at Kew during the past year. It is of dwarf habit, with small leaflets and deeply cleft corollas, like *S. Commersoni*, and bears very small tubers, none at present grown exceeding 1 inch in diameter; but they are very numerous, and when cooked extremely floury and pleasantly flavoured.

The practical result of these investigations is that Mr. Baker recommends the culture of *S. Maglia* and *S. Commersoni* for hybridisation with *S. tuberosum*, with the object of raising a type of Potato that should, if possible, unite the prolificness, good quality, and size of tuber of the latter with the damp-enduring character of the former, which would be likely to render Potatoes more adapted for our moist climate, and, therefore, less liable to disease. The importance of this suggestion, and the reliability of the facts upon which it is advanced, render it well worthy the attention of all who desire to improve this vegetable, and the thorough manner in which the investigations have been conducted merit the highest commendation.

If, as appears more than probable, that the species, *S. Maglia* especially, possesses greater inherent vigour, and is naturally adapted for a moist climate, it necessarily has claims to the attention of hybridisers of distinctly greater importance than those of *S. tuberosum*, which for the past century cultivators have been so busily engaged in improving. As far as regards the productiveness and quality of our best varieties there is little to be desired, but a greater disease-resisting power is urgently needed. It is the more likely that this may be imparted by the robust and moisture-enduring species *S. Maglia*, since experience has shown that vigour of plant is an element of success, inasmuch as with scarcely an exception what are termed "disease-resisting" late or main crop varieties are strong growers with more or less ligneous stems and robust foliage. It is also established as a rule with only the few exceptions necessary to prove its existence, that an excess of moisture in the soil and the air at a critical period of the plant's growth is the great predisposing cause of the murrain that devastates the crops. It is seldom virulent in dry years, but always more or less so in wet ones. Varieties that ripen very early, and especially when grown in dry warm positions, are rarely seriously

attacked, and never unless the rainfall is abnormally great when they are approaching maturation; and grown under glass there is no disease except by some mismanagement in ventilation and watering. The path of safety lies in the direction indicated—a race of Potatoes, the offspring of a moisture-loving stock, the habitats of which are the low coast line and ravines where *S. Maglia* is found, and not that of a plant whose home is on dry mountain sides, as in the case of *S. tuberosum*.

If peradventure Mr. Baker shall have proved that the labours of cultivators and hybridisers have been devoted to improving the wrong Potato, and if his investigations should result in varieties being raised naturally adapted to our climate, he will deserve a national tribute which will be shared by the great establishment which he adorns.

HORTICULTURE IN 1883.

WHILE our good friend "Wiltshire Rector" always gives us his sound and cheery advice for the time that is before us, and shows us how best we may benefit others even when carrying out our own plans, it has generally fallen to my lot to give at the beginning of a new year a *résumé* of that which has just closed; and its bearings on the present we all delight in ere they pass from memory, and in these days of express speed they very soon do so. They are like the landscape through which we rush in the "Flying Dutchman." We catch a glimpse of the stately towers of Windsor, of lovely reaches of our queen of rivers, of quiet homesteads and snug country homes; but before we have time to think much about them they are gone from view. And so with events now. The events of months and years rapidly fade from memory, and with them the lessons which they teach. It is not, then, I think, a useless task to bring the past year to mind and see what it has done for horticulture and what notable things it has brought before us.

In a review of our subject the proceedings of the Royal Horticultural Society naturally claim prior attention. Although in consequence of the greater exhibition at South Kensington no adequate space was left for grand horticultural shows there, yet the Society was enabled to carry out an exhibition at Chiswick—the Apple Congress, which for its practical utility and far-reaching benefits must be noted as the horticultural event of the year, and that it will give a great stimulus to the cultivation of this most valuable of our fruits there has been already ample proof, while the report which is yet to come will no doubt be appreciated by all who cultivate it. The fortnightly meetings of the Society still maintain their interest; while the evening meetings at the Linnean Society were so successful that they converted most of those who went there into so many Oliver Twists, "wishing for more"—not on the same night, as some of the papers were too long, but for more meetings of a similar character. What its future is to be no one seems able to forecast: let us hope that more prosperous days may be in store for it. The exhibitions at the Royal Botanic Society have been successful; and as delightful promenades with good music and a fashionable company they cannot, with the one remaining element, fair weather, fail to be so. The Crystal Palace Company under its new management is evidently looking upon its flower shows as one of its best cards. The schedules of the exhibitions during 1883 were more liberal than has been for some years the case, and there is a promise of those of 1884 being still more so: and yet flower shows as such do not seem to pay! I wonder whether there was truth in what a well-known horticulturist said to me the other day. The fact is we want to do away with big shows in London for a few years. People have had too much of them, and if they ceased for a time would then ask for them and appreciate them when they were held.

I think perhaps one of the most interesting exhibitions of the year was that held by Mr. Bull at Chelsea, where for weeks during the height of the season a beautiful collection of flowering Orchids was visited by the most eminent cultivators and by vast numbers of the nobility and gentry. Not only were the plants themselves models of good cultivation, and beautiful in the profusion and variety of their blossoms, but they were arranged with great taste; and certainly the remembrance of the sight is to me, and I doubt not to many others, one of the most pleasant memories of 1883. The *furore* for Orchids seems to grow with ever-increasing ardour—sale after sale at Stevens' and Protheroe & Morris' disperse thousands and tens of thousands of Orchids over the kingdom. The older growers seem to have lost none of their zeal, if we may judge from the prices given for them (the £243 given by Sir Trevor Lawrence for *Vanda Sanderiana*), while new growers are starting up in all directions. Nor is this to be wondered at. The mysteries that once surrounded Orchid-growing are fast being dispersed; the abnormally high temperature

is being discarded, for it is seen that they do not require it, and of course this means less expense (though, from the prices given, few Orchid-growers seem to think much of this); and their varied and most lovely forms, their often most delightful perfume, their continuous flowering, so that the Orchid house is never without flowers, all combine to make it what it is—one of our most popular flowers.

Of other flowers there has not been, I think, during the past year anything very noticeable. The Rose still maintains its popularity, and the success which has attended Mr. Bennett's hybridising (although I dissent as much as ever from the term "pedigree Roses," and hold my hand still with regard to Her Majesty), has given hopes of still further improvement. It would seem that when flowers get to that pitch of perfection that there is very little difference from year to year on the new varieties that their day is to a certain extent over. It would be difficult to say what further improvement can be effected in the Pelargonium either in the Show or Zonal varieties, and I suppose in consequence of this the Pelargonium Society feels that its work is done. Can, again, the Begonia advance much further? With flowers 6 inches in diameter and of all shades of colour, with double varieties of great beauty and substance, we are tempted to ask, Is not their day nearly over also? The past season has brought before us some very remarkable new varieties, so remarkable that we may well ask, What next? The single varieties raised by Mr. Laing and the double from abroad are alike wonderful and beautiful.

That horticulture is throughout the country not only holding its own but progressing is, I think, manifest to anyone who goes much about the country. The ever-varying pleasure which it gives must make it popular, while the low price at which so many of its productions are now offered, and the liberal spirit which marks most horticulturists, tend still further to increase it; and we are delighted to find how the taste for herbaceous and alpine plants is on the increase. In all directions we see the old bedding-out system giving way to the long-neglected old-fashioned flowers, and those who follow out this pursuit have stores to go to which our forefathers knew nothing of. The recent introductions in these classes far outnumber the old-fashioned flowers, and the immense variety and great beauty that exist amongst them will, I hope, still more encourage others to cultivate them.

As ever, the death roll for the last year numbers amongst it many well-known and deeply regretted names. The genial and hearty Harper Crewe, one of our most distinguished herbaceous and bulbous cultivators, is sadly missed; then we miss the portly form and honest face of Henry Hooper. The gentle Edward Pilgrim is no more with us, and the closing days of the year have brought us the sad news of the melancholy death of Thomas Speed, and thus it is each year. Solemn notes of warning to us who remain!

One noted name still is with us, fresh and vigorous as ever—in fact, recovering its youth—cheering with its smile many a youngster to whom we veterans must give way ere long—the Journal. Age does not seem to add a wrinkle to its brow or a grey hair to its head, and I but, I am sure, echo the wish of all its readers when I say, *Esto perpetua*.—D., Deal.

ROOT-CULTIVATION OF VINES.

IN common, no doubt, with others similarly situated, I have often been questioned as to the cause of and remedy for Vine roots going down into the drainage or subsoil, and not taking possession of the surface half of the border; and very recently we had some interesting remarks on this subject from an amateur in the south of England who was at the time engaged in getting his Vine roots out of the depths. It is, of course, very undesirable, especially in certain subsoils, that the roots of Vines should be chiefly in the depths of the border, and not active and numerous near its surface. The cause of such a tendency on the part of Vine roots may be an inherent disposition to go downwards, or there may be several conditions which force the habit in them. At all events the roots of Vines can be led to multiply themselves at the very surface of the border, and in the great majority of, if not in all, circumstances it is most desirable that they should do so.

The fact that the roots of Vines require to be as carefully cultivated as their stems is in numerous instances not systematically recognised nor acted upon. What is considered an orthodox border is made, and young Vines planted, and while every necessary detail connected with the welfare of the stems is attended to with care, that upon which success mainly depends—namely, the culture of their roots, is not attended to with the regularity and care that is necessary to keep them where they ought to be—near the surface of the border.

The first step in leading the roots in their downward course is in mixing into the border a quantity of ordinary manure from

the farm or stables. Naturally the roots have the instinct, if the term may be applied, of going where they get most to feed upon; and planted in a border thus enriched, with the surface of it left uncovered, the roots go down in search of the more moist and consequently more available elements of nutrition at a distance from the exposed drier surface. If at first no such manure is mixed in the soil, but instead of it bones and other appropriate manures, and immediately the Vines are planted the farmyard manure be placed on the surface as a mulching, and it be kept moist all through the season of the growth of the Vines, the moisture and elements of nutrition in the surface dressing will attract the roots. It is not necessary nor desirable—should the first summer be dry and hot—that more water should be applied than will keep the surface third of the border moist by artificial waterings. The bottom will take care of itself, and if the upper portion is thus kept moist the roots will keep to it as sure as water runs downhill.

Some time late in autumn or in winter when the Vines are at rest the mulching should be removed, and also the surface soil till the roots are reached, and immediately over them should be laid 3 or 4 inches of fresh loam and horse droppings in the proportion of four parts to the former to one part of the latter, and also a few barrowfuls of old mortar or charcoal rather finely pounded, then over the whole throw as much rough stable litter as will keep the frost out. After the Vines have begun growing in spring remove the litter and prick into the surfacing of loam artificial manures in the proportions directed by their vendors. Then, or some time before there is any chance of drought affecting the surface of the border, carefully lay on the 3 or 4 inches of good farmyard manure, and keep it moist as formerly described. If this process is repeated every season it will keep the roots at the surface in the greatest health and activity, and it is an operation that does not involve much labour. This is what I would term "root-cultivation," and when it is neglected the roots go down in search of moisture and nourishment because they cannot get such at the surface when these operations are not systematically attended to.

The whole of our borders here are so treated annually a regularly as the pruning is done, and when the mulching is removed the roots are found swarming close underneath it. No ordinary dung was put into the borders at first, and the surface of the borders has never been dry. I hope these remarks may be useful to some of your numerous readers who may perhaps be wondering why the Vine roots are so deep down instead of being very near the surface.—D. THOMSON, *Drumlanrig*.

"SINGLE-HANDED"—A SAD CASE.

"WHERE is that excellent man 'Single-handed?' Can he not join usefully in the interesting discussion on Vines?" is the inquiry in a letter before me, and not by any means the only one that has been written of the same purport.

The time has arrived when the readers of the Journal should be made acquainted with one of the saddest episodes in the life of a gardener that I trust it will ever be my lot to chronicle. Only on two occasions have I had the painful pleasure of visiting this truly excellent man, accomplished gardener, and earnest temperance advocate—once in his bed in a Scottish cottage, from which he was not expected to rise, and again, and recently, similarly prostrate, hovering between life and death, with a group of children and sorrowing wife around him, in a strange place 400 miles from his Scottish home.

That distance he had travelled to enter on an appointment, but before he could take charge he was stricken down. When the skill of the best medical men was exhausted and their patient was regarded as sinking, he asked for Grapes, since everything, even water, caused blood-vomiting. These were given tremblingly, and to the astonishment of all were retained. It was then my great privilege, through the generous kindness of private friends, whose valuable aid I now gratefully record, to maintain a steady supply of Grapes, and in a fortnight such was their healing power that nourishing liquid food could be taken. It was given under medical supervision, and for three weeks, and again by the kindness of friends, with apparent benefit; but a sudden and serious relapse has occurred, and now, should our friend recover, the case must be a protracted one.

Grapes are the sheet-anchor. If any persons who may be able to send a bunch, or would otherwise like to assist one of the worthiest of men, will communicate with me, I shall be glad to reply to their letters.

"Single-handed" has now been prostrate for nine weeks and is solely dependent on his resources, necessarily vanishing, since he has not been able to follow his occupation regularly for some eighteen months, and his illness has prevented him joining the Gardeners' Benefit Society. Although he is not likely to want, still, as there must be many who would be glad to share in his restoration (if that blessing is vouchsafed), I now accede to the strenuous wishes that have been pressed during the past month by those who know the case, and make the painful circumstances known.

I may add that his illness has been the direct result of laborious work, and that the vital organs are quite sound; on that account there is hope that if he survives the present serious affliction he may with great care and

a long rest from exhausting physical labour eventually regain his lost strength, and practise successfully and teach effectively in the calling that he loves so well.

With the object of assisting in a small way I have undertaken to distribute seeds from his beautiful hybridised Alpine Auriculas, of which so many applicants on a previous occasion failed to obtain a supply. Packets will be sent for 2s. 6d. each in rotation to those applicants who remit the requisite amount and enclose a stamped directed envelope, and if desired the money will be returned should the stock be inadequate to meet all demands. The seed now at disposal was gathered last summer and kindly given to the raiser of the plants to help him in his unfortunate position by his late employer.—J. WRIGHT, 171, Fleet Street, London, E. C.

WALDSTEINIAS.

NEXT to Geums none of the Rosaceæ compare favourably in point of compact habit and floriferous character with the Waldsteinias. This genus, like many more, has undergone some changes, and at one time

Fig. 9.—Waldsteinia trifolia.

between Dalibardia, Comaropsis, and Waldsteinia numbered over half a dozen species. In the "Genera Plantarum," the first has been sunk under Rubus, the second under Waldsteinia. This changing naturally resulted in a reduction of species also, and now only two or three at the most really good and distinct garden plants compose the genus.

Waldsteinia trifolia, Koch (*W. sibirica*, DC.; *Comaropsis sibirica*, Tratt).—The plant shown in the accompanying fig. 9 is a native of southern Europe, and although long introduced to this country its merits do not seem to be appreciated as they deserve to be. For planting in all sorts of positions, either in exposed places on the rockery or in the deep shade of woods, it will be found very useful, as it grows in both with equal success. It is also a very desirable plant for a place near the front of a mixed flower border. Dwarf in habit, it seldom attains a foot in height, and the loose corymbs of Buttercup-like flowers are really very attractive, and are developed profusely. The leaves, which are divided into three leaflets, are borne on creeping, chiefly underground stems; they are slightly hairy, and serrated at the margins. This plant seems to run into the *W. fragarioides* of DC., which is a native of America, and is only distinguished from *W. trifolia* by its oblong petals and glabrous capsules. In *W. trifolia* the petals are round, the capsules hairy. They are much alike in habit and profuseness of flowers.

W. geoides.—A native of Hungary, and an old and much-admired

cottage garden plant. It is easily distinguished from the above two by its large, round, five-lobed leaves and smaller flowers. It grows about 6 inches high. Beginning to flower in May it extends over several months. It grows in shady woods, and is an admirable plant for covering bare spaces under trees.—M. S.

SUMMER AND AUTUMN CAULIFLOWERS.

It often happens that when the earliest batch of Cauliflowers is cut there follows a period when these are not only scarce but not to be had at all. It has been my practice to sow in a box at this time a few seeds to produce plants which follow those now in the open quarters. The plants merely need to be kept growing slowly, and in March require to be pricked out in frames or in a sheltered position in the garden, to be thence transplanted to the ground set apart for them. We also transplant from seed beds those which have stood over the winter, but as a rule these are not satisfactory, buttoning being very general among them. Those from seed sown now do not button. Curiously enough, if autumn-sown plants are placed out in January they have very little tendency to button. For the past few years I have confined myself to the Early Dwarf Mammoth for the summer supply of this highly esteemed vegetable. Early London is a good variety, but I have not always obtained it true to name, and in growth it is much stronger than the Dwarf Mammoth. The new forcing varieties are useful for early work, and one of the best early autumn varieties is King of the Cauliflowers, though I may say that I find no difficulty in keeping up a supply with the first named and Autumn Giant, of which a few seeds are also sown now, and treated in the same way as stated for the early varieties. To those who may have a difficulty in deciding upon Autumn Giant or the newer Eclipse for an autumn supply, it may be noted that both are excellent. Both require very rich soil and plenty of space to do them justice, the former having an advantage in being later than Eclipse, while it may be obtained quite as early by sowing as above recommended at this time.

There is also this to be noted in connection with these late sorts as distinguished from earlier varieties, they must have a long season of growth, and require a richer soil to grow them well. A little guano as a surface dressing will do wonders in bringing on early Cauliflowers, but Autumn Giant must have the something in the soil, though surface dressings are not to be despised in its case either.—B.

VINES BLEEDING.

This has been a source of anxiety to many gardeners, and numerous remedies have been tried from time to time, some of which are efficacious. Styptic specially prepared is excellent, and will prevent bleeding if applied in time, so as to be properly hardened. In the discussion respecting "Stored-up Sap in Vines" I learn the Vine in bleeding loses nothing but water at a certain season—that is, before the leaves expand. If this be a fact I need not trouble myself any more about my Vines bleeding or placing styptic on in good time. I can give my Vines two gallons of water for every one they lose in sap. Mr. J. Muir in the *Journal* of April 5th, 1883, gave us an account of a Vine that had lost gallons. He invited predictions as to the effect on the Vine, but none were made as far as I saw. He said he would let us have the result, and I for one have been looking for the fulfilment of his promise.

I have a small house occupied with Vines of Lady Downe's, which on the score of bleeding have always been a mystery to me. I generally prune them about the 1st of February each season. From this time until near the end of the month all seem lifeless, but just as the Vines and the house are being cleaned bleeding commences, and in the mornings the sap is dropping all through the house, and continues for about eight or ten days. It then ceases, the Vines seem as lifeless as they did a fortnight previous, and for three weeks or a month there is no perceptible start in the growth. This I cannot understand, but if the Vines were to start bleeding and continue doing so until they were in leaf I could. Perhaps Mr. Wm. Taylor, "Non-Believer," or some of the many able correspondents who took part in the "stored-up sap" discussion will be able to explain it, and I am sure to the benefit and interest of many others. Though I took no part in this discussion I cannot help voting for Mr. Taylor, as I have always seen Vines, &c., liberally treated the season before starting strongly; and, on the other hand, those treated badly always did correspondingly the following season. I believe all fruit trees "lay up a store," according to their resources, and hence Pear and Apple trees have only a good crop every alternate year, and Vines are very similar.—COMBER, *Co. Down*.

CULTURE OF POINSETTIA PULCHERRIMA.

THIS plant is a very great favourite with all who possess a stove. It is one of the most useful flowering plants for decorative purposes at this season of the year, but half a dozen good healthy plants with fine bracts make more show than twenty unhealthy plants, therefore a few hints on the culture will be acceptable to young readers of this *Journal*.

After the plants have flowered they should be pruned to about half a dozen eyes and removed into a little bottom heat. They will produce abundance of shoots in a very short time, and when

these are about 2 inches long they may be taken off with a heel. Insert about eight cuttings in a 48-size pot, pressing them in firmly with a dibber, taking care not to bruise them, or they will not strike. Employ a compost of equal parts of good sandy loam and leaf soil, and plunge them in a little bottom heat—they will strike freely. They should then be potted off into 60-sized pots, using a compost like that recommended for old plants. After they have recovered from the shift they should be hardened gradually to the same temperature as the old plants. As soon as the roots become well established they should be placed in 32-sized pots. These plants will make good specimens by winter, suitable for associating with Ferns.

About the middle of June the old plants should be pruned to within two eyes of the previous year's pruning. Then they should have all the old soil shaken off the roots and potted in a compost of two parts fibry loam, one part leaf soil with some decomposed fowl manure, a little sand, and a 3-inch potful of bone dust to the barrowload of soil. Pot them rather firmly. They should be started in a cool frame with a south aspect, keeping the frame closed till they are growing freely; then ventilate a little to prevent their being drawn, breaking off all the weak shoots that are not required, leaving two or three, which will be quite sufficient if large bracts are desired. When about 1½ inch long they should be plunged in some coal ashes in a sunny position. The soil should never be allowed to become dry or the leaves will fall; they should have a supply of liquid manure about three times a week. Before the frost appears the plants should be shifted into a frame, keeping them close to the glass, covering them on cold nights, and ventilating freely on favourable occasions. As soon as the winter commences they must be housed in a temperature of 48°, falling to 45°, still keeping them near the glass, for the less growth they make in the autumn the larger the bracts will be. When the bracts are showing the plants may be removed to a stove temperature to develop, and when fully expanded they may be placed in an intermediate house. Under this treatment I have seen heads of bracts fully 13 inches in diameter, with leaves down to the rim of the pot.—C. H. STEPHENS, JUN., *Lyne Gardens*.

HOTBEDS AND THEIR MANAGEMENT.

THERE are many young gardeners who do not know the proper way to make a hotbed. I believe it was thought amongst old gardeners to be one of their qualifications, and from my father who is one of the old school I had my first and only lessons in the art. A number of gardeners and amateurs have to trust to hotbeds for producing their Cucumbers, Melons, propagating, raising seeds, &c.; and if it is desired to grow good Cockscombs a hotbed is the right place to produce them. Young gardeners of the present day have not the makeshifts to contend with that our fathers had in their young days, and by only having experience with the modern appliances of the present time, are generally in a fix when they first take a situation on their own account, if they do not find all the modern conveniences. Of course they are expected to produce as good crops of Cucumbers, Melons, &c., as was expected from gardeners they lived under who had all suitable convenience for producing them; but to succeed they must adapt themselves to circumstances and make a hotbed for a start.

If Oak or Beech leaves can be procured so much the better. Add to the leaves the same quantity of long stable dung as will make the bed, and turn the heap two or three times to prevent overheating, which will cause the material to dry, and if it was made up in this state very little heat would be procured; if it should get a little dry, or the dung may be rather dry in itself, it should be well watered to cause it to heat satisfactorily, as a lasting heat is what is required, not a violent heat at first, which is exhausted by the time the material is in a proper condition for making the bed. Mark a space 8 inches wider than the frame intended to place on it, drive a stout stake into each corner, and then commence placing the material in, but not in layers as usually done, or trampled down, but commence at one end, well shaking the dung out, and work to the other, beating it down as the work proceeds, especially the edges, with the back of the fork, when it will bind well together. About 4 feet 6 inches to 5 feet is a good height. After the bed is made the frame must be placed on. Place two smooth planks across the bed about 2 feet from each end; then with a man at each end, or corner as required, lift the frame up, place the back of the frame on the end of each plank, when you can easily run it on the bed without anyone trampling on it. Leave the lights open about an inch to allow rank steam to escape.

If the frame is required for Cucumbers or Melons place turves grass side down over the bed; but if for propagating, a layer of cocoa-nut fibre or ashes will be the best. The lights should be open slightly night and day at the back of the frame; and when the mats

are placed on at night do not let them hang over the opening, except in the case of cold winds from the quarter they open towards. When the cuttings, or whatever there may be in the frame, require sprinkling or watering, which is generally on fine days, do it early in the afternoon. The water used should be of the same temperature as the bottom heat. Close the frame when the cuttings have been sprinkled, opening it slightly two hours after. When the bottom heat is declining a good lining of fresh material must be placed around the frame, packing it well around the sides. When the frame requires attending to, do not tread on the lining, but have a pair of steps at the back of the frame. Hotbeds are very useful for forcing Asparagus, Mint, Tarragon, Sweet Basil, and Tomatoes.—A. YOUNG.

EARLY PEAS.

THE useful letter from Mr. Barker (page 25) anent the growing of early Peas recalled to my memory a method I saw adopted by Mr. Melville at Glenlee. In numbers of instances Peas are sown and grown to a certain stage under glass, and then after a gradual hardening-off planted outside in borders. Different men have different methods; some grow them in pots, some in ordinary boxes, and others again use turves. The plan adopted by Mr. Melville differs from these, and is, I think, superior to any of them. He uses boxes or troughs formed something after this style. A number of small blocks of wood are obtained and a notch cut out of each thus— In this notch two thin boards, corresponding in length to the breadth of the border where the Peas are to be grown, are placed, and the box is complete. After they have been filled with soil and the Peas sown two nails should be driven into each block and a string passed over the top of the box. This keeps the blocks in their proper place, and enables the boxes to be carried with convenience whenever it is necessary to shift them. When planting time arrives the simplicity of this method will be further seen. Supposing the ground to be thoroughly prepared beforehand, a notch corresponding in size to the box is formed, care being taken that it is quite level. Two men can easily transfer the Peas to their final position. The strings holding the blocks must then be cut away, the boards being held together with the hands till they are placed in the notch prepared for them. The boards may now be taken away and a little soil passed round the sides of the Peas, and the row is complete. It is advisable to draw a little earth round them and stake them at once, as this shelters the young plants and gives them a better chance to succeed.—CALEDONIAN.

ADVANTAGE should be taken of the present unusually mild and open weather for the time of year to make good sowings of the following excellent varieties of Peas in well-prepared ground, in rows (the number of which must be determined in accordance with the demand for the produce in each individual establishment) running north and south, and 8 or 10 feet apart, the intervening space being planted with three or four rows of Cauliflowers later on—viz., William I., Laxton's Supreme, Carter's Telephone, and Ne Plus Ultra. The above Peas, which should be sown in the order in which their names appear, will make a good succession to the produce of the early varieties, of which we shall speak presently, and yield a daily supply of well-filled pods from the end of June for a month or five weeks hence; the supply being continued thence till late in the autumn by the produce of later sowings of the same or kindred varieties made at intervals of a fortnight up to the second week in June.

Early Peas.—The reason why I have given precedence in this paper to varieties and sowings of the same, from which Peas will be only ready for gathering by the time the supply from those of which I now write has been nearly exhausted, is because the seeds of the latter, owing to the special treatment to which they are or will be subject, do not require to be sown so early by a week or two, and then though the ground should happen to be in the firm grip of "Jack Frost" the fact need not in the least interfere with this procedure—viz., the sowing of early Peas in pots. For this purpose use 3-inch pots three parts filled with light soil, into which about eight or ten peas should be placed, and then covered with some of the same soil. The pots should then be removed to an early vinery or Peach house, and thence when the Peas have made a couple of inches of growth to a cooler and more airy house, where they can be gradually hardened off preparatory to being finally planted out in sunny borders later on. However, the method of procedure to be then followed will be communicated in another paper. For this crop we shall sow, and here recommend to be sown, Laxton's Earliest of All, Day's Early Sunrise, William I., Suttons' Ringleader, and Emerald Gem, all excellent early varieties, and from which peas may be expected to be gathered the third week in May, should we be favoured with ordinary spring weather.—H. W. W.

TROPEOLUM TUBEROSUM.

HAVING met with great success in the cultivation of this splendid climber, I thought a few hints respecting its requirements would be of service to many who have not given it a trial. I purchased a tuber of it in January of last year and at once potted it and brought it slowly on in a cool greenhouse, and when the weather was sufficiently warm planted it out against a wall having a south aspect, where it soon made rapid progress and was admired by all who saw it, not only for its pretty foliage, but its mass of blooms.

Sandy loam is the best compost for it, and during growth plenty of rain water at the roots; manure in any shape is not needed. This single

tuber covered a space of 20 feet, and when its beauty was past I lifted the root carefully, and found I had a cluster of tubers numbering thirty-seven which had multiplied from the single one which I had planted; some of them larger than the one I cultivated in the first place.

The greater number of failures, I believe, are caused through too much feeding with manure, which causes these plants to produce foliage in quantity in place of blooms.—J. D. M., *Essex*.

GARDENERS EMIGRATING.

I SHALL be much obliged if any reader of the Journal can give me any information relative to the colony of New South Wales as regards gardening. I see advertisements in the newspapers for young men to go out as emigrants, Vine-dressers being specially mentioned. As I intend going out there soon, I should like to know the Vine-dresser's duties and average rate of wages. I have had a good practical experience in fruit-growing indoor and out, having acted as foreman at one of the largest Grape-growing establishments in the kingdom. Any information will be thankfully received by—A FOUR-YEARS READER.

I AM to emigrate to New South Wales, Australia, soon. Can any of your numerous readers inform me of any good firm that I could apply to in pursuit of a situation? near Sydney preferred. Also any reliable firm near Melbourne (Victoria)? Any information will be thankfully received by—J. S., *Co. Down*.

CULTURE OF USEFUL PLANTS.

Primulas.—Sow *Primula* seed in March in pans, place them in a cool house and cover them with glass, which should be removed when the seeds have germinated. When large enough prick the seedlings off into pans in a finely sifted compost, and transfer them to a warm frame, giving them a position near to the glass; a Melon or Cucumber bed just started being suitable. When well rooted transfer them into 60-size pots. Soil, two parts loam, one of peat, half finely sifted well-decayed manure, half sand, and a little rough grit. A warm bed should have been specially prepared for them, which would rise to about 70°, and with a covering of 6 inches of soil to prevent the injurious gases from the dung rising into the frame, placing the pots close to the glass. Repot the plants when necessary, and by the last shift the bed ought to be renewed and increased, so as to give plenty of room, and a little fresh mixed with it is all that is required to raise the heat. Never have the soil too moist, or, to use the general expression, keep on the dry side. In the beginning of October transfer the plants to a good dry and light shelf in a greenhouse or cool vinery, water very sparingly and with weak liquid manure. To keep up a supply seed ought to be sown at different periods.

Bouvardias.—Plants of these that have ceased blooming should be cut down and transferred to a light and warm house to commence growth. When ready, which will be the end of January or beginning of February, cuttings should be taken if possible with heel of the old wood and inserted in 48-size pots, a mixture of finely sifted peat and charcoal being employed. Place the pots in a frame in a propagating house, and when the cuttings are rooted transfer them singly into 60-size pots, and place them on a shelf near the glass in the same or a similar house. In June place them in a frame or cool house where they can be syringed twice a day. Shift them when they are sufficiently advanced into a compost of loam, peat, charcoal, cow dung, and sand. Great attention must be paid to watering and pinching the shoots to make good plants. Fumigate if aphides are troublesome. In October remove them to a warm house and give supplies of weak liquid manure.

Marantas.—February is the month for potting these, for which use a compost of three parts peat and part loam and sand. Grow them in a good heat, placing, if convenient, in a brisk bottom heat. Great care should be taken in crocking the pots, as they require a great quantity of water, and it is necessary it should not remain stagnant. Syringe twice a day, and in case they are not plunged stand them in pans kept full of water during summer. Much less is required in winter.—A FOREMAN.

SPECIAL SOCIETIES.

"A FEW old fogies are fond of Auriculas, Carnations, &c.—so very fond of them that they go to the trouble to promote special exhibitions of them, thinking that a certain portion of the public would be pleased to see them. The public, or at least a portion of it, see and applaud. The fogies are satisfied, and do not trouble their heads about 'national utility.'"

The above was written last week by Mr. James Douglas, and I must say I have never before seen such an honest confession, as far as it goes, from a florist. There can be no doubt about the "old fogey" aspect of the question, and a member of that fraternity is qualified to speak on the subject. Mr. Douglas has not, however, told the whole truth about special societies. One main reason why the "old fogies" encourage these is an eye to business, and the sale of their seeds and plants. The successful Auricula growers are probably about one in a hundred among gardeners and amateurs, but the greater the number that can be prevailed upon, by means of shows, &c., to embark in pot-Auricula culture the better for the "old fogies" and the worse for the garden culture of a pretty flower that was intended for our flower borders and rockeries, and not for the frame or glass house of "old fogies," who truly "do not trouble their heads about national utility," and I therefore conclude that the title, "National Auricula Society," which they have adopted lately, is a delusion.

Mr. James Douglas is in the secret counsels of the fraternity, and ought to know, and be thanked for his frankness on that point. It is too good to pretend, after such an admission, that Auricula shows are "promoted" with the object of "pleasing the public" or even a "certain portion of it." Your special florist is simply a person with more than usually restricted sympathies and views on flower culture, who "does not trouble his head about national utility." A special society to improve the Potato, for example, or some other subject of importance, one can understand; but one like the Auricula Society, which it is confessed has no useful purpose to serve, and which serves none, is not worth encouraging or defending, and certainly not worth making so much noise about.—BORDER FLOWER.

WHEN we begin to answer questions on any subject connected with these special societies it seems that there is no end to them. Your correspondent, "Auricula," now wishes to know how the large growers can be prevented from competing against the small ones. I really cannot say. "Exhibitors in A and B cannot compete in C and D," but if a large grower chooses to compete in C and D there is no rule to prevent him. I do not think it is often done, and I fancy even in the case mentioned by "D., Deal," that gentleman made a mistake. The grower referred to was the late Mr. Thos. Woodhead, and he was not the man to take advantage of a small grower. The only way is for the Press to notice any flagrant instances of it. A man who had a surplus stock of 1000 plants ought not to have competed in C and D when the choice was given him of two out of the four classes, and I do not think it was done. At one time all the classes were open, but at that time also there were few exhibitors. Now that the alteration has been made it must be left to the honour of the exhibitors. It would scarcely do to define the number of plants an amateur should grow.—J. DOUGLAS.

SOME friends of the Societies under discussion will be inclined to regret that Mr. Douglas has undertaken the championship of their cause, for while practically admitting their defects he has represented them in a far worse light than I should have thought of doing. If the societies are confined to "a few old fogies" who do not "trouble their heads about national utility," what claims have they to the title they have adopted, to the publicity that is accorded them in the press, and to the funds they are so assiduous in collecting? If they had chosen to follow their hobbies in a private manner, none could have objected; but they have courted popularity, and "national" institutions must be necessarily exposed to the criticism of a utilitarian age. When funds are being expended for any presumably "national" purpose, we have a right to know whether such funds are being applied to the best possible advantage, and in the case of the special societies I consider this is not done.

As to the number of prizetakers at these shows, there is no question whatever that the projectors and those who appear to take the greatest interest in the matter are really those who are most successful, and therefore their testimony cannot be regarded as impartial. For instance, at the National Auricula Society's Southern Show last year I find, from the reports given in the gardening papers, that there were thirteen prizetakers and nearly 100 prizes offered, while at the Carnation and Picotee Show there were only eleven prizetakers. At the latter, too, in the classes for single specimen blooms, sixty-five prizes were offered and divided amongst four exhibitors, one of whom gained thirty-three of the total—a great victory undoubtedly, and one that should be "proclaimed from Land's End to John o'Groat's," but to the uninitiated it savours much of monopoly. Cannot this be remedied?—X.

As an admirer of the Auricula, but not an exhibitor, I do not exactly see why those who choose to contribute to a special society should not do so if it affords them pleasure. Auricula shows are very beautiful; indeed it is questionable if there is so much real beauty in a similarly small space as in a collection of these charming alpine plants. The Auricula exhibitions in London have enormously improved since the present Society was established, and this fact presumably satisfies the subscribers, whether they win prizes or not, or, in fact, whether they compete or not. It is not claimed, I think, that the Society in question is perfect. Most organisations of this nature are open to improvement. The question is, In which way can the National Auricula Society be improved? What rule can be altered or change effected to widen its popularity? It is to this question that your critical correspondents might usefully direct their attention, and at present I fail to see that anything has been suggested that will render the shows more generally satisfactory.—NON-EXHIBITOR.

VINE ECONOMY.

MR. TAYLOR'S questions (page 37) show what a vague and uncertain meaning he attaches to the term "Economy of the Vine." According to his statements it might be something in the ground and not in the Vine at all. I decline to recognise his unintelligible and unscientific interpretation. I understood him to use the term in the same and proper sense that physicians employ the words "economy of the human body or system"—referring to the circulation of the blood, assimilation, growth, &c., or in other words functional development. The economy of the Vine is like that of other plants—especially those in its own section—in these respects. It lives on the same food, thrives in the same soil, feeds in the same way, breathes the same air, has a similar structure and system to other plants, and finally dies just in the same way. Mr. Taylor's notions of analogy are indicated by his comparison of the Vine with Geraniums and Roses, &c., and his knowledge of his subject is

shown by his question, "Will the Gooseberry root grow wrong end up?" Clearly he does not yet know that it will do so, and many other plants besides. I thought the inverted Gooseberry cutting was a familiar example with most people. For a more intimate acquaintance with this subject I would refer Mr. Taylor to modern works on plant-structure and physiology.

I expected an answer from "Credo" about elaborated sap, and I here beg to submit that elaborated sap *does not* return to the leaves, and that such a thing has never been proved notwithstanding the confident "undoubtedly" of "Credo."—NON-BELIEVER.

THE annual meeting of the ROYAL HORTICULTURAL SOCIETY will be held at Kensington on February the 12th. The gentlemen recommended by the Council as officers for the year are as follows:—President, the Right Hon. Lord Aberdare; Treasurer, William Haughton; Secretary, Major F. Mason; Auditors, John Lee and James F. West. To fill the vacancies in the Council caused by the retirement of Sir Chas. W. Strickland, Bart., James McIntosh, and Henry Webb, the Fellows recommended are the Right Hon. Viscount Enfield, Professor Michael Foster, F.R.S., and Frederick Du Cane Godman, F.R.S.

— THE INTERNATIONAL POTATO EXHIBITION will again have the advantage of facilities, generously granted by the Royal Horticultural Society, for the trial, culture, and cooking of new varieties submitted for certificates of merit. Persons intending to compete are requested to send, carriage paid, not more than eight varieties, six fair samples of each, to Mr. A. F. Barron, Horticultural Gardens, Chiswick, near London. At the same time a communication on the subject should be made to the Honorary Secretary of the International Potato Exhibition, 23, Upper Thames Street, London, E.C.

— THE DUNDEE INTERNATIONAL HORTICULTURAL EXHIBITION will be held in the Drill Hall and grounds of that town on the 11th, 12th, and 13th of September, 1884, when upwards of £1000 will be offered in prizes. Very liberal provision is made for exhibits of fruits, seventy-one classes being devoted to them. About 120 classes are appropriated to plants and cut flowers, and nearly thirty to vegetables. In all the leading classes the prizes are liberal, the most important being that for sixteen sorts of fruits—namely, £20, £15, and £10; while for a collection of twelve sorts, £15, £10, and £5; and in a third class for eight sorts, £10, £6, and £4 are offered, these being open to all.

— A CORRESPONDENT suggests that the balance in the hands of the PELARGONIUM SOCIETY be given to the Gardeners' Royal Benevolent Institution on the ground that "if added to the funds of the Auricula and Carnation and Picotee Societies it would practically be placed in the pockets of some half-dozen individuals."

— "P." writes respecting DELPHINIUM NUDICAULE as follows:—"In 1882 I saved seed of the above and sowed it in heat in the spring of 1883, growing the seedlings and planting them out during the summer. They gave us a beautiful show of flowers in the autumn, and are still in bloom. I intend to place them under glass and plant them out in the spring. They were so beautiful that I almost feel inclined to employ them for bedding-out this year. Have any of your readers bedded them out, and with what results?"

— THE same correspondent also, referring to ANOMATHECA CRUENTA, remarks:—"I have been agreeably surprised by plants of the above from seed sown last spring without any extra care. The seed was sown in pots in ordinary soil kept in a cool pit, and they have given us a fine display of lovely flowers. They are now perfecting seed, so that we may have a display of them in autumn treated as annuals."

— MESSRS. PAUL & SON, Cheshunt, send us examples of REAL AUTUMN ROSES in the form of a few tops of the good old Bourbon Rose Souvenir de la Malmaison, and the new H.P. Grandeur of Cheshunt, off two rows they are pruning for very early flowering. They seem to illustrate the perpetual habit it is so desirable to obtain in new Roses, every shoot terminating in a flower bud.

— MR. T. S. WARE, Hale Farm Nursery, Tottenham, sends us a few flowers of the DOUBLE WHITE NEAPOLITAN VIOLET, COMTE BRAZZI, gathered from plants in the open air, to show the size, purity, and fragrance of the variety. We have previously referred to this beautiful Violet in commendatory terms, and these examples fully confirm the opinion we had formed respecting it. They are very fine, of good substance, with long stalks, and possess a most powerful and lasting odour.

— AT the special sale of ORCHIDS at Mr. Stevens' rooms, King Street, Covent Garden, last week some good plants of *Odontoglossums*, *Cattleyas*, and *Lælias* were shown in flower, and formed quite a pretty display. Some of the principal prices realised were the following:—*Lycaste Skinneri alba*, twelve guineas; *Lælia Crawshayiana*, four guineas; *Phalænopsis amabilis Dayana*, six guineas; *Cattleya Trianae*, fine variety, six guineas; *Odontoglossum Edwardi*, £7; *O. Andersonianum*, nine guineas; *Cypripedium villosum*, nine guineas; *Cœlogyne cristata*, six and a half guineas; and *Lælia autumnalis*, six and a half guineas.

— AN American contemporary states that at Craig, in Braidentown, are two of the LARGEST GUAVA TREES IN FLORIDA. They are 30 inches in circumference and 30 feet in height. From the fruit of these two trees, two years ago, 200 lbs. of jelly were manufactured, besides supplying the neighbours round about with fruit to their heart's content.

— REFERRING to the request for a good WHITE CARNATION FOR WINTER, a correspondent observes:—"I think if 'X.' gives The Queen a trial it may suit him. Although it flowers during the summer, if propagated now it would probably be a good winter bloomer. It was pointed out to me by a good authority as a great acquisition, and is very pure and free."

— ON Monday evening last the annual meeting of THE ROCHDALE AURICULA SOCIETY was held in the Lyceum, Rochdale, when the Secretary presented his report and statement of accounts. The Show on the 2nd of May was a decided success from the florists' point of view, and although the financial success was not so apparent, yet the statement showed that the balance against the Society was under £1. C. M. Roys, Esq., was re-elected President; Saml. Barlow, Esq., Stakehill, Wm. Botton, Esq., Warrington, J. H. Lancashire, Esq., Deeplish, and Thos. Watson, Esq., Horselans, were appointed Vice-Presidents; the veteran, Mr. James Cheetham, was appointed Chairman of the Committee, and Mr. Brodie, Mitchel Street, Rochdale, was re-elected Honorary Secretary. The date of the Exhibition for 1884 was fixed for the 3rd of May, and a liberal schedule of prizes was arranged.

— ARRANGEMENTS have been made for a series of six HORTICULTURAL EXHIBITIONS AT THE CRYSTAL PALACE during the present year, a total amount of £1400 being offered in prizes. The season will commence with a Show of Spring Flowers on April 4th and 5th, to be followed by a Summer Show on May 23rd and 24th, a Rose Show on July 5th, Dahlia Show September 5th and 6th, Autumn Fruit and Potato Show October 7th to 11th, and Chrysanthemum Show November 14th and 15th. The exhibitions will be arranged and superintended by Mr. W. G. Head, and the liberal prizes to be offered may be expected to result in some handsome and successful displays.

— MR. J. E. WAITING, Grange-over-Sands, writing upon FLOWERS IN WINTER remarks that "herbaceous plants are all starting. Polyanthus and Primroses have been flowering since October, Snowdrops during the past fortnight. Laurustinus has been one mass of bloom for two months. Gloire de Dijon Roses are still covered with buds like those enclosed; the Rosemary is showing flowers, and the yellow Jessamine covered with blooms. Pear-tree flowers are opening, and the mild sunny days we have had remind us of the coming summer. Much injury is sure to follow such weather sooner or later. My border varieties of Auriculas have all finished blooming weeks ago." With this note were sent flowers of Polyanthus, Primroses, Wallflowers, Laurustinus, *Jasminum nudiflorum*, Rose buds, Rosemary, and twigs of fruit trees with much-advanced buds.

— RELATIVE TO FRAGRANT ROSES a Yorkshire correspondent observes:—"I see amongst the most fragrant of the Hybrid Perpetual Roses Duke of Edinburgh, which is scentless, and John Hopper, which is very poorly scented, sometimes not at all. Most of the others named

on page 540 last volume are richly scented, but may I call attention to the Duchess of Edinburgh, which is included? Surely this Rose has gone out of cultivation; if not, it ought to be discarded. Mr. Simons on page 4 mentions in his list of fragrant Roses Mabel Morrison. Well, if this Rose is fragrant, then all Roses are." Have soils and situation any influence in this matter? With us John Hopper is decidedly fragrant, Duke of Edinburgh only slightly so, but a very good grower finds it admired for its perfume as well as its colour. Mabel Morrison we have not found to be fragrant, yet others may have done so. How, then, are we to account for its variability?

— A BOOK of great interest to all dwellers in the country has been produced by Mr. Harrison Weir, whose love of Nature and skilful pencil are well known. It is called "EVERY DAY IN THE COUNTRY," with 400 illustrations, and is in the form of what is called "a birthday book," and on every day in the year some natural objects are referred to, accompanied by a pretty woodcut illustration. Let us take as an example this 24th day of January, and we shall find these records—"Chaffinch sings," "Spring Crocus flowers," "Robin builds," "Skylarks feed on grain, insects, worms," and this is illustrated by the figure of the chaffinch. So on throughout the whole year, and consequently there are 365 objects illustrated with original drawings from Mr. Weir's prolific pencil. Besides these there are six pretty chromo-lithographic illustrations. We highly commend this to the heads of families as an incentive to the young to study natural history.

— THE ANNUAL MEETING OF THE ESSEX FIELD CLUB for the election of new members of Council and officers will be held on January 26th, 1884. The following members agreed, at the meeting on December 15th, 1883, to retire from the Council—Mr. H. J. Barnes, Mr. J. T. Carrington, Mr. R. Meldola, and Rev. T. W. Peile. To fill the seats so rendered vacant the following are proposed for election—Mr. H. J. Barnes, Mr. F. C. Gould, Mr. D. Houston, F.L.S., F.R.M.S., and Mr. R. Meldola, F.C.S., F.R.A.S. The following members are recommended by the Council for election as officers for 1884:—President, Prof. G. S. Boulger, F.L.S., F.G.S., F.R.M.S., &c.; Treasurer, Andrew Johnston, J.P., D.L. (late High Sheriff of Essex); Secretary, William Cole; Assistant Secretary, Benjamin G. Cole; and Librarian, Alfred Lockyer.

— MR. SHIRLEY HIBBERD'S "GARDEN ORACLE FOR 1884" is now issued, and contains, in addition to the usual calendrical matter, lists of new and select plants, fruits, and vegetables, with much information respecting Potatoes, including classification, synonyms, and a descriptive catalogue of 450 varieties, a selection of the best Apples at the Chiswick Congress, a useful summary of the Agricultural Holdings Act for 1883, and a variety of instructive matter.

— "M. S." writes:—"Since my last note regarding the cultivation and manufacture of RHEA OR CHINESE GRASS, a meeting has been held in the St. Michael's Hall, George Yard, Lombard Street, having for its purpose a project for extending its cultivation in the territory of the Maharajah of Johore. The meeting was convened by Messrs. G. H. Brogden & Co., and presided over by Mr. Needham Crowe. It appears that the formation of a company was contemplated for the purpose of acquiring 21,000 acres of land for 999 years from the Maharajah, part of it having already been chosen with the view of disposing of it to enterprising cultivators at the rate of £1 per acre, and the granting of licences for the use of two processes—one the Favier process, by which the stems are operated upon by means of boilers at the rate of 4000 in twenty minutes; the other the Frémz-Urbain process, taking the ribbons thus produced and turning them out ready for the spinner. It was stated that the cost of the prepared material at present was practically—allowing for losses—£100 per ton, and that by the above processes the selling price may be reduced to £60, at which price it would compete fairly with flax. It would be well if farmers in this country also were to give it a fair trial. I am confident it would pay far better than many of the crops grown by them at present, and with the advantage of requiring less attention and also less expense."

— A CORRESPONDENT writes as follows on the EARLINESS OF VEGETATION IN COUNTY MEATH:—"Plants in flower outdoors are Wallflowers, Arabis alba, Pansies very bright, *Pyrus japonica*, Polyanthus and Primroses as free as April, including the double yellow, white, and purple varieties. In the wood may be seen the Germander

Speedwell and common Buttercups in full flower. Rhododendrons are also showing their colour; we are lifting some for pots, which will soon give us a useful display. The Cabbages remind me much of the London market gardens in May; some old stems running fast to flower which were expected to afford useful produce in March and April."

— "OBSERVER, *Yorkshire*," sends the following list of WINTER FLOWERS. "We have had extremely mild weather during the past few weeks and we have the undermentioned plants in flower. *Limnanthes Douglasii*, *Midlothian Stocks*, the *Filbert*, *Schizostylis coccinea*, *Lamium maculatum*, *Saponaria calabrica*, *Scabiosa caucasica*, *Bellis perennis*, *Ranunculus repens*, *Roses*, various *Perpetuals*, *Lychnis dioica alba*, *Ranunculus aeris*, *Alyssum maritimum*, *Veronica syriaca*, *Doronicum caucasicum*, *Erysimum pulchellum*, *Iberis TomThumb*, *Myosotis dissitiflora*, *Daphne Mezereum*, *Jasminum nudiflorum*, *Oxalis floribunda*, *Calendula officinalis*, *Rosa sempervirens*, *Lamium purpureum*, *Fragaria vesca*, *Borago officinalis*, *Garrya elliptica*, *Pyrethrum Golden Feather*, *Hypericum calycinum*, *Eranthis hyemalis*, *Viola odorata* The Czar and others. *Forsythia viridissima*, *Caltha palustris plena*, *Lunaria biennis*, *Alyssum variegatum*, *Viola tricolor* various, *Aubrietia deltoidea*, *Chrysanthemum segetum*, *Rose Gloire de Dijon*, *Chinese Chrysanthemums*, *Erica carnea*, one of the best plants we possess for the winter; *Cheiranthus Cheiri*, *Rosa Laurenciana*, fine for beds and edging large beds; *Hepatica triloba alba*, *Delphinium nudicaule*, *Hesperis matronalis*, *Physalis Alkekengi* in fruit, *Tritoma Uvaria*, fine owing to the absence of frost. Our *Hellebores* are remarkably beautiful this season, in different shades of colour, and the foliage bright; and last, but not least, *Anemone stellata*."

A WINTER FRUIT GARDEN.

THERE is no fruit tree that approaches the Orange; the beauty and profusion of its flowers, the sunny golden fruit set off and relieved by the splendid glossy evergreen foliage combine to place the Orange in the premier rank, a peer amongst its peers. With these qualities it is not a little singular that the dismal old orangery, crowded with straggling bitter fruit should have been considered sufficient for its cultivation, and that in rich England it has not been established as a winter fruit tree as indispensable to a well-kept garden as the pinery or vinery. My house has about fifty trees in it studded with golden fruit, and has been a special pleasure since the beginning of November, the season when the fruit assumed the rich, sunny, golden hue peculiar to healthy Oranges. The temperature has ranged from 50° to 60°, not much above the outside air, the ventilators being open from nine in the morning till four in the afternoon, causing no discomfort from heat in the house and no fear of catching cold on quitting.

All variety is charming, and though Oranges resemble each other very much there is a considerable difference. I have the Maltese Blood and some twenty sorts of St. Michael's, all possessing some distinctive peculiarity, notably the Silver, the Prata, and the White. The Tangerine grows as easily as a Medlar, and fruits as generously.

The Bergamot Lemon is large and delicious in flavour, and the tiny Bijou is aromatic and pungent enough for a giant, producing fruit of a pale straw plentiful as leaves, the whole tree, leaves and fruit, being redolent of perfume enough to make a Scotchman deify it.

Shaddocks, Limes, and Citrons require no greater heat than Oranges, and flourish amicably in the same house; useless for use, but adding an additional interest to the house.

There is no prettier dish for the dessert than the Orange gathered with a stalk of leaves; the fruit is fresh, fragrant, deliciously juicy, filling a room with its perfume. A well-arranged Orange house, large and lofty, would probably pay its expenses and leave some profit, no expensive forcing being required; it would be unequalled as a winter promenade, and I recommend the idea to those who wish to promote the attractions of our winter seaside resorts.—T. F. RIVERS, *Sawbridgeworth*.

ELECTION OF CARNATIONS AND PICOTEES.

THE BEST SIX IN EACH CLASS.

HAVING had numerous inquiries in reference to this matter during the past year, and not being able to answer them to my own satisfaction, I communicated with several of my friends and brother florists, as under: Mr. J. Booth, Failsworth, Manchester; Mr. Robert Lord, Todmorden; Mr. J. Douglas, Great Gearies, Essex; Mr. Charles Turner, Royal Nurseries, Slough; Mr. S. Brown, Birmingham; Mr. Ben Simonite, Sheffield; Mr. G. Geggie, Bury, Lancashire; Mr. S. Hartley, Headingley, Leeds;

Mr. Edward Adams, Swalwell, Gateshead; Mr. William Mellor, Wakefield; Mr. Thomas Maddock, Lofthouse Hall, Wakefield; Mr. Thomas Bower, Bradford; and Richard Gorton, Esq., Eccles, near Manchester; to obtain their selection of the best varieties. Lastly, my own selection is added, making fourteen lists, from which I have compiled that which follows, giving the number of votes obtained by each variety. My esteemed friend Mr. Dodwell was unable to furnish me with a list, as he is suffering from rheumatism, for which I was heartily sorry and trust that he will soon recover. A list like this has many surprises, and no doubt many will be disappointed, as I have been myself whilst compiling this election. I propose, in addition to the present list, to furnish each individual's selection of the best six in each class. In nearly all cases the full six were given, with one exception only (R. Gorton, Esq.), who says he thinks that four of each is a good representative list. This will make a slight difference in the quantity of votes, but is not of moment in the quantities given.

CARNATIONS.

Scarlet Bizarres.

—G. RUDD.

JOSEPHINE DE MALINES PEAR.

YOUR correspondent "C. B." (page 29) asks if others have found their Josephine de Malines Pears ripen early this season. Although February and March are given as its season for ripening in some nurserymen's fruit catalogues, I think it more often ripens in December than at that time. We commenced using it this winter on December 14th, these were gathered on October 25th from a south wall. We are now using the same variety gathered from a west wall on the same date, and have another lot not yet ripe which were not gathered until November 29th, also from a west wall. Thus we are enabled to have a supply of this best of winter Pears for nearly two months. I say best, as I consider it has no equal in its season. It remains good some time after it is ripe without deteriorating in flavour and never shrivels. It is a prolific kind both on the Pear and Quince stocks; the fruit is always free from cracks and scabs. In this locality and heavy soil it does not succeed as a pyramid, the wood does not become ripened enough to form fruiting spurs.—A. BARKER, *Hindlip Gardens*.

DURING the last few years I have noticed the above excellent Pear spoken of in the horticultural press as ripening earlier than usual. I have also noticed in fruit catalogues generally that the time of ripening is stated from April to May. Has anyone ever tasted it in good condition in May? My experience of it is, that the latter end of November and through December is the time that this excellent Pear is in good table condition. If the fruits have not been properly matured it may keep a month or so longer, but then the fruit is not in such good condition as it is when ripe during the season I have stated. A good late Pear that will not deceive anyone in the time of ripening is Bergamot Esperen.—A. YOUNG.

PAST v. PRESENT WRITERS.

ADVICE TO YOUNG GARDENERS.

MRS. MALAPROP long ago declared that "comparisons are odorous," and the old lady, though using her selection of words somewhat malapropos, was nevertheless in this saying strictly true to the letter. Unfortunately the "odour" in "comparisons" is generally unpleasant. We are all of us so much affected by our own ideas, and think, alas! too frequently that they must be the best. I have had a share amongst the past, and, thanks to our Editor, am yet occasionally seen among the present writers. I am much older than our Chaplain, as far as connection with our Journal goes, for it is more than thirty years ago that I penned the first words that I ever sent to the office. I almost feel again the trepidation with which I despatched that first missive, and I think I recollect the subject on which I ventured to write was "A Matter of Fact." Necessarily, then, as this was more than thirty years ago, I am getting on—disposed, therefore, to be a praiser of the days past rather than of the present; and I could not help thinking with "A Philistine," what could be the matter with "H., Notts," and that something in the Christmas feeding must have disagreed with him. If so, I am sure we all hope this has passed off, and that in the papers he will soon give to our Journal he will help to keep up its character for practical utility. So far as my humble judgment goes, the character to which "H., Notts," has

borne such willing testimony in the years long since gone by has not departed. I would name writers of the present day whose thoughts add a lustre to any page, but doubtless they would not thank me; and though my fingers itch to pen their names, I forbear, believing this, that when they are gone, which God grant may be in the very distant future, their loss to our Journal will be deeply felt and widely lamented, although no doubt that then there will be good men and true to take their place, for

"New crops of mushroom boys succeed
And push us from our forms."

Having learnt the little I know of our Journal's subjects chiefly from its pages, and acknowledging my indebtedness to many writers both of the past and the present, I venture to think that the verdict of present readers of the Journal, even though they be old enough to recollect it as the "Cottage Gardener," will not endorse the sentiments of "H., Notts."

There is one other point about these comparisons, and that is a little sting which generally leaves a sense of soreness. Now, I have always felt peculiarly that there was a great bond between the writers in our Journal, and that however hard the blows they dealt each other in discussing certain subjects, this was generally done in search of truth, in kindly feeling, with the button on the foil, though the remarks might be pointed. I, for one, do not wish this feeling to disappear. I count some of my most pleasant acquaintances, acquaintance-ship which has ripened into friendship, through the pages of our Journal, and this bond of union which unites the past with the present I should like to see increased. I fear "H., Notts," in his comparisons lessens it.

There is an old story that a dyspeptic gourmand, as fond of his money as of his good feeds, dining quietly with a medical friend, thought he might, under the charitable influence of good old port, extract from his friend rules for his own treatment without the necessity of parting with a fee. Accordingly over the fire he began his complaints, ending at last with "Now, doctor, what do you advise me to take?" "Well," said the host quietly, "I advise you without delay to take advice." Now it does seem a little odd to me that "A Young Gardener," for instance, rather disdains taking advice. He will probably read our Chaplain's sermon. I hope he will. The wonderments are not all good, and it must be allowed that there are a great many more wonderments now-a-days. If only these do not interfere with work, well and good; but it must be remembered that to a gardener his work is often something like that of a woman's in the old couplet, which ran something like this—

"Man's work stops at set of sun,
But a woman's work is never done."

This is especially the case if, as well as gardening, we have other duties, and then the wonderments are apt (it is human nature, and just now I am writing to myself as well as to young gardeners) to trench on time that ought to be otherwise employed. When wonderments do this, when mind and body are unrefreshed by them, they are better honoured in the breach than the observance—they are best let alone. All work and no play there is little fear of in the present day; and if the future men turn out dull it will not be for want of wonderments, whilst it must be allowed by all employers of labour that the great tendency of the present day is to shorten hours. I am not so certain that this is all gain, neither do I quite see in the case of many gardeners, even though appliances in aid of labour have so greatly improved, how this shortening of time can be carried out in their case, and their duty to the interests committed to their care be strictly fulfilled as well. It is well that our Chaplain does remind us sometimes that we are to be tried by One who seeth not as man seeth, and happy is the gardener, as indeed any other worker, who keeps this thought continually before him, and humbly strives to act up to it.

My experience leads me to think that that man is the happiest whose wonderments take the form of hobby connected with his work. How many gardeners, aye, and very successful men too, have thus made their pleasures an offshoot, as it were, of their work, and by their pleasant labours enlightened the rest of the world on some points in natural history or improved some neglected plant. One word more. Sincerely do I hope that young men will take to heart our Chaplain's warning about the respect due to those above us. These are days when the tension between classes is great, and yet one member cannot suffer without all suffering with it. Youth in the present day has immense advantages. Education presses on, but if its effect be to make one proud and conceited, it will be an evil instead of blessing. The more sincerely education is appreciated the more surely will the humble worker feel that he has touched but the crust of the matter, and that there are numberless mysteries still to fathom. He need not, like the old warrior, sigh for more worlds to conquer.

For obvious reasons, laying no claim to any credit in past or present pages, I drop my usual *nom de plume* for that of—A LOVER OF THE JOURNAL, PAST OR PRESENT.

It was not my intention to refer to the above subject again, but I think a few words in support of the commendable article by "Wiltshire Rector" in your issue of January 3rd will not be out of place, and I hope all young gardeners read it with intense satisfaction. He neither blames nor accuses, but simply gives good advice, which I hope will be fully appreciated and beneficial.

I feel much gratified to see in the index pages of the last volume that never before in a like period have so many communications been received from young gardeners. This I consider speaks well of us, and also looks as if there will be some scribes left when all of the present good old stock are gone.

I agree with "T. L." that head gardeners are not altogether faultless. Although quite a youth I have served under gardeners of very different character and very different in their treatment of those under their charge. A few encouraging words when deserved assist a young man greatly in his onward path. At the same time I think that head gardeners ought to keep and see that others under him keep the rules of the establishment to a letter, for it is certain if rules are not kept at the top they will not be kept at the bottom.—T. R. M.

THERE seems a little misunderstanding about the advice of "A Working Gardener," and the comment of "H., Notts." The way I read the letter of "A Working Gardener" I could not see much, if anything, to find fault with, and I am very much inclined to think some at least of your correspondents are somewhat blind to their own interest. What interest can it be for "A Working Gardener," "H., Notts," or any other member of the fraternity to cast a stone at the present generation of young gardeners? No, it was not intended to hurt their feelings, but I take it to be a gentle reminder that we must not slumber, but be up and doing. "Let him that standeth take heed lest he fall" was somewhere near, if not the text from which your correspondent preached. It is useless for young men to say they can do this, that, and the other. They cannot serve two masters, as I know from experience, and this I strive earnestly to impress upon the minds of the young men under me. It is very few years since I was a journeyman, and by no means without fault; nor do I wish to be considered spotless now. Let young men read the articles in question again, and I think they will be of the same opinion as—A YOUNG HEAD GARDENER.

[We have two other excellent letters on this subject which will be published; for some others we fear space will not be available, but "H., Notts," will be accorded space for reply if he desires it. In the meantime we suggest that the whole subject be well considered, and in a few months hence if the sound advice that has been given is turned to account its value will be appreciated. We have no fear that the gardeners and writers of the future will not be as competent as those of the past and the present; but that is not enough. Our hope is that they will be better cultivators and better writers, both in their own interests and in those of the art that they should ever strive to improve.]

THE TULIP.

THE fortnightly meeting of the Manchester Horticultural Improvement Society was held in the old Town Hall on Thursday the 17th inst., Mr. Bruce Findlay in the chair. There was a large attendance.

Mr. F. Robinson read a paper on the Tulip. He said a history was connected with this plant in some respects differing from most floral productions. The Tulip is a native of the Levant and the warmer parts of Asia, and is very common in Syria and Palestine. In the year 1559 the Tulip was rapidly distributed through all parts of Europe, being brought from Persia by Conrad Gesner, an eminent German physician and naturalist. Early in the seventeenth century the special cultivation of particular varieties was first prosecuted to a considerable extent in the Netherlands, and the price of the roots was higher in value than that of the most precious metals. In the years 1634 to 1637 the passion for the possession of choice Tulips became so strong amongst the Dutch, that dealing in them became one of the most important money speculations, and the bulbs were sold and resold at enormous prices. For one root of the Viceroy variety £250 was paid, while for Semper Augustus a person agreed to give 4600 florins (equal to £460) with the addition of a new carriage and a pair of horses. Another agreed to give twelve acres of land for a single root of this sort. As late as the year 1854 Mr. Groom of Clapham catalogued show Tulips at enormous prices: Duchess of Cambridge, Princess Mary of Cambridge, and Miss Eliza Seymour were sold at one hundred guineas each, others at fifty, twenty-one, and ten guineas per root. In the following year, 1855, the whole of Mr. Groom's collection, which consisted of over 200,000 roots, was sold by auction, as they stood in the rows, at very low prices, and from this time the Tulip as a show flower declined in the public favour at a rapid rate. Mr. Robinson described the different sections of the late or show-blooming varieties—viz., bizarres, bybœmens, roses, and breeders, the three first being again divided into the feathered and flamed forms. The soil needed, the planting time, and the treatment were fully and clearly stated; and he next passed on to the early-blooming sorts—those mostly used for the decoration of our greenhouses and conservatories, as well to the broad stretches of beds to be seen in the spring in public parks and private gardens, where they are grown in masses in the flower beds. An approximate estimate of the numbers sent from Holland annually of a few of the leading sorts would be about as follows:—Scarlet Duc Van Thol, 800,000; White Pottebakker, 300,000; Golden Prince, 500,000; White Queen Victoria, 500,000; and Thomas Moore, 100,000. The total number of flowering bulbs of the Tulip yearly exported by the Dutch florists amounts to over 5,000,000 bulbs. The commercial value for a flower at the present day of a new variety of early Tulip, if of unusually fine quality, would be about £1, being only about one-tenth the value of a new Hyacinth. The reason for this difference is that it would take fifty years to get up a stock large enough to send out; while with a Hyacinth, which multiplies rapidly, the same results could be produced in ten years.

In the discussion which followed much light was thrown upon the manner in which the new bulbs were reproduced. For in planting the bulbs in autumn and growth taking place in the spring the flower stem is plainly observed rising from the centre of the bulb, but when the bulbs are taken up after flowering the flower stem is on the outside of the one taken from the ground. A process has gone on all through the growing season by which the nutriment first taken up by the roots and passed through the leaves, and receiving fresh material from the air, is again passed down the leaves and deposited at the base of the flower stem, and gradually built up into a new flowering bulb for the following season. Mr. G. Lunt, Mr. Astley, Mr. Tait, M. Findlay, and the Hon. Secretary (Mr. W. Swan) took part in the discus-

sion. It was announced that Mr. B. Findlay would give his paper on the next meeting night, January 24th; subject, "A Plant: What is it?"

PLANT-FORCING.

WITH the new year the forcing of plants and bulbs may be said to commence with earnestness, and many indeed are the means and contrivances resorted to with a view to having different plants in flower out of their natural seasons. It seems almost needless to say that success, both in regard to quality and quantity of bloom and the precise time at which individual plants are required to produce their flowers, depends in a great measure on two things—viz., the state the plants are in, and the treatment they have received preparatory to being forced in the first place; secondly, heat and moisture. Unless a certain amount of preparation and the necessary requirements of a plant have been attended to before its introduction into a comparatively high temperature satisfactory results need not be anticipated. To explain the matter more clearly I would say—speaking in a broad sense—that plants intended to be forced must not be taken direct from the borders and put into pots and into a strong heat at the same time, as such a process has a very great tendency to defeat the object in view. Such plants, for instance, as *Azalea pontica*, *Rhododendrons*, *Lilacs*, *Deutzias*, *Guelder Roses*, *Andromedas*, and other hardwooded examples, should be potted early in the autumn months and be plunged in coal ashes in a shady place, there to establish themselves till within eight or ten weeks of the time they are wanted to produce their flowers. Herbaceous and bulbous-rooted plants, such as *Spiræa japonica*, *Dielytra spectabilis*, *Solomon's Seal*, *Lily of the Valley*, *Heliborus niger*, *Hemerocallis flava* and *fulva*, *Hyacinths*, *Tulips*, *Narcissus*, *Crocuses*, &c., must also be potted in the autumn and plunged in ashes out of doors for a reasonable time before being forced. The reasons for these preparations are obvious enough to most practitioners; not so, however, perhaps to the tyro, but the fact still remains that unless a plant is well established and has an abundance of fresh healthy roots, its buds and flowers do not respond to the heat with such freedom as is necessary to insure the highest success. This rule, however, must not be taken in too literal a sense, as it has exceptions. I have lifted large bushes of *Syringas* and *Persian Lilacs* 6 feet high and as much in diameter, these having been transferred to a forcing house without further delay, and the result has been all that could be desired; but then it should be stated that they were taken up with a large ball of earth and an abundance of roots, and at a time when the flow of sap was most easily excited—viz., February and March, the roots, of course, being afterwards covered with two or three barrowloads of soil, well watered, and the stems syringed. There is one other very important point connected with the early forcing of plants, especially those of a hardwooded nature, and that is stating them in too high a temperature. The falling of buds, immature expansion, and weak spindly flowers wanting in colour and odoriferousness where this quality is a characteristic, are due in many instances to a certain amount of disregard and negligence on the score of heat, and are not unfrequently attributed to a totally different cause.

What temperature should plants be introduced into when forcing commences? is a question I have sometimes had put to me, and my answer has invariably been, That depends very much on the time of the year and the state of the weather at the time it is purposed to begin. No hard-and-fast line can be drawn, but it cannot be wrong to allow the inside temperature to be 10° or 15° higher than the outside, bearing in mind to let the one fluctuate with the other, and when the buds have commenced moving increase the temperature by another 10° or 15°. In practice this rule will, in the great majority of cases, be found a good and safe one to follow, much more so than a given minimum and maximum of heat irrespective of the external elements. To insist on a thermometer inside a forcing house standing at 60° or 70° during a cold winter's night when there are several degrees of frost is not, in my opinion, conducive to health and vigour in plant life. Further, I would say that such a state of things would greatly tend to produce the opposite effect, for to maintain anything like this temperature under such conditions as I allude to, unless there is an extraordinary amount of heating surface, means that the pipes must be so hot as to preclude the bare hand from remaining on them for more than a second or two, and when this is the case the atmosphere cannot be other than in a very dry state, a circumstance which, as is well known, is productive of evil consequences to all kinds of vegetation in a growing state. An early vinery with a good bed of fermenting material in the middle, made of loam and stable litter, is a very good place for forcing such plants as have been named, the bed being used when the heat has subsided sufficiently for plunging the pots in. In this matter, however, great caution and judgment must be exercised, otherwise serious consequences in the way of burnt roots owing to the violent heat will assuredly follow, and which no subsequent care and attention will rectify. A want of fore-

Fig. 10.—*SENECIO MACROGLOSSUS*.

thought and neglect on this point very often result in dearly bought experience.

With such bulbous-rooted plants as Hyacinths, Tulips, and Narcissus, also Lily of the Valley, it is a very good plan to place inverted flower pots over their crowns for a short time when first put into heat. This has a greatly benefiting influence, especially with the last-named, which when thus treated throws up its leaves and flowers simultaneously. Syringe well overhead two or three times daily all hard-wooded plants, such as Azaleas, Rhododendrons, Deutzias, Lilacs, Syringas, and kindred plants up to a within a day or two of their first flowers expanding, at which period they may be moved to the conservatory or some other cool and airy structure.—J. HORSEFIELD, *Heytesbury*.

IVY-LEAVED SENECIOS.

FROM the plebeian Groundsel to the handsome *Senecio speciosus* and *S. pulcher* is a great stride, but this exceedingly large family comprises an even greater range of variation than there is between those species. One of the most remarkable groups is that which includes the species from the southern hemisphere and other tropical or arid climates, mostly distinguished by their succulent stems and leaves, strangely imitative forms, and diverse habit. Among those the climbing Ivy-leaved Senecios are especially noteworthy and really ornamental, though but seldom seen in gardens and known to comparatively few horticulturists.

It would be difficult to persuade the uninitiated that the remarkable plant *Senecio macroglossus*, represented in fig. 10, is a relative of our common Groundsel, yet such is the fact, and that is not the strangest part of its character. The leaves are so exactly like the smaller-leaved varieties of Ivy that when not in flower it is frequently mistaken for them by visitors to the succulent house at Kew. It is one of those strange examples of vegetable mimicry which Mr. Leo Grindon has so interestingly reviewed in his little work on that subject, and none of those he has noted is more striking than this. The two genera *Hedera* and *Senecio* are widely separated in natural arrangement, and the particular species in question are respectively from northern Europe and southern Africa, and therefore neither geographically nor naturally related; yet the African Groundsel produces a leaf the exact counterpart of the European Ivy in form, colour, veining, and even somewhat in texture, though rather more fleshy. The habit of the *Senecio* also closely resembles the Ivy, the shoots scrambling about in an irregular and careless manner; but the stems, of course, are not furnished with the small roots that aid the Ivy in its progress up trees and over old walls or ruins.

In the flowers resemblance to another plant may be noted, but this time much more closely related—namely, the *Etoile d'Or* variety of *Chrysanthemum frutescens*. The colour is a trifle lighter and rather more creamy, yet bright and clear; the form of the flower heads, and especially of the outer florets, being very suggestive of the *Chrysanthemum*. They are produced very freely, and at a time of year when flowers are particularly appreciated—namely, from December to Feb-

ruary, lasting either on the plant or if cut and placed in water a week or more. This is no mean recommendation, and should alone be sufficient to rescue it from its present position amongst neglected plants.

Senecio macroglossus has been found on the Table Mountain, at the Cape of Good Hope, and in other districts of South Africa, seeds having been first sent to Kew by Mr. Sanderson in 1868, and from these probably the first plants grown in this country were raised. Sir Joseph Hooker states that he has heard that in some continental or other cities

this plant is grown in rooms and trained round the walls near the ceiling, and from its peculiar succulent structure it would, no doubt, be fitted for such dry positions, though its strength would be severely tested in ordinary English rooms. The best position for it is a greenhouse or cool stove, but the former is preferable, as it cannot endure a moist atmosphere. It is not particular as to compost, light sandy loam with a little leaf soil or old decayed manure being suitable, and if grown in a pot this must be thoroughly drained and water very carefully supplied. The best plan is, however, that adopted at Kew, where it is planted out and trained up the roof of the house.

An allied species, *S. mikanioides*, is known as "Nice Ivy," and in St. Helena as "Ground Ivy," both names being derived from the resemblance of the leaves to those of the Ivy.—L. CASTLE.

THE PROFESSIONAL GARDENERS' FRIENDLY BENEFIT SOCIETY.

IN reference to this Society, the seventeenth annual report of which was published on page 39 last week, we shall answer some inquiries and anticipate others by directing attention to the leading features of the Association. We do this the more willingly since in our remarks on the excellent and admirably conducted "United Horticultural Benefit and Provident Society," established in London (see page 349, October 25th, 1883), we stated that "our primary object was to benefit gardeners and not to advertise the claims of any particular society; and if any other institution exists of the same nature that offers greater advantages to its members, and is equally and indisputably safe, we will on being made acquainted with it not the less readily urge its claims for support."

The Society under notice, which is established and is so well managed at Leeds, is not adduced as offering "greater advantages" than the London institution. The two Societies are different in their working, both being safe, sound, and equally well conducted, and engaged in a most commendable and important work.

The principle of the London Society is to act not only as a benefit society but as an insurance and bank to the members, the surplus funds after the demands for sickness are met being invested for each member, and become his property absolutely. The payments are based on a scale that time has proved ample for meeting the demands of sickness and insuring a substantial residue—namely, 6d. a week for insuring a payment of 10s. 6d. weekly for twenty-six weeks, and half that sum for a similar period, besides small contributions to the benevolent and management funds.

In the Leeds Society there is no surplus banked for the members; but the management appears to be based on the principle of dispensing the greatest amount of benefits in sickness, and providing grants at the death of members and their wives by the lowest possible scale of payment. In this respect the results are remarkable, and we suspect unparalleled. In return for 3d. a week the payment of 10s. weekly is secured for twenty-six weeks, then 5s. weekly as long as the member is ill and conducts himself in accordance with the rules of the Society. This 5s. may indeed amount to a pension provided a member should be incapacitated by illness for an indefinite time. That these privileges can be maintained for such a trifling sum is very gratifying. It is evident that the moral character and sober lives of gardeners have a powerful influence in contributing to the result, while there is always the greatest reluctance on their part to relinquish their duties, and for members to place themselves on the funds of a society for a slight ailment; and when compelled to do so it is incumbent on them from the circumstances of their position to resume their work at the earliest possible moment. "Class privileges" is a term not always of pleasant import; but it is clear that there are class privileges possessed by gardeners by which they have the utmost right to benefit, and they can do so by joining such provident societies as these with much greater advantage to themselves than by becoming members of general benefit societies that include persons of every calling, and practically regardless of their habits of life. We are not aware that there are any such institutions as the two in question that can afford to dispense anything like equal benefits for anything like similar rates of payment. We commend them to all members of the craft who desire to make some provision for illness, and especially to young gardeners, every one of whom should take advantage of their position and the facilities offered by becoming members of one or other of these excellent societies.

At the first glance it seems almost incredible that the Leeds Society can offer so much in return for such slight outlay, but experience has proved that it can do so safely; and with a

regular accretion of young members its accumulated fund of £675 will increase. There is a rule, however, to provide for emergencies to the effect that if the accumulated fund should fall to £1 10s. a member, that an additional sum of 1d. or more a week be paid until the amount is equal to £2 10s. per member, when the contributions will be reduced to the nominal sum of 3d. weekly. It is pleasing to record that this rule has never been called into operation. So far from this being so the amount per member, instead of falling to £1 10s., has risen to upwards of £6. The Society is open to the membership of all gardeners, and applicants have to sign a declaration that they have worked as a gardener for seven years successively (five years for members up to twenty-one, three years up to eighteen years of age), and should their statements ever be detected as false they lose all claims to the benefits of the Society. It is thus difficult for any but *bonâ fide* gardeners, who must, moreover, be men of good character, to get enrolled as members. Initiatory fees are charged varying in amount according to the ages of applicants.

The northern Society is further supported by a number of honorary members, and the good work of the Committee is recognised by the municipal authorities and local dignitaries of Leeds, some of whom invariably attend the anniversary dinners at which all the benefit members who can do so assemble.

At the monthly meetings papers on gardening are read, and discussions held thereon. In order to encourage the production of papers prizes were offered for the first time last year by a leading banker, Mr. Oxley; but though eight papers were read only three were placed in competition, and as the prizes are repeated under different conditions, the members expect greater competition and better results next year. The three prize papers are in our hands, and inverting the usual order we shall publish the third first, and the others, or abridgments of them, will follow in due time.

We have only to add that the address of the Secretary of the Professional Gardeners' Friendly Benefit Society is Mr. W. Sunley, Bacchus Hill, Moor Allerton, Leeds, who will forward rules in return for stamped directed envelopes, and give any information that may be needed to gardeners who may desire further particulars of the Association. Our advice is that gardeners should study carefully the rules of both the excellent Societies mentioned, and decide which they consider the most advantageous in each individual case. We have observed that gardeners who have not joined societies such as these, and who are now too old to do so—forty-five years of age being the limit—regret that they were not acquainted with their existence sooner. With the sole and entire object of helping those who are engaged in gardening operations to help themselves by making provision for illness we have made these Societies more widely known than before, and the Secretary of one of them, we are glad to know, has had his labours enhanced accordingly. The Secretary of the other will not object to similar work, the purpose of both being to do good to their fellow workers in the craft in which they are engaged.

PROPAGATION BY CUTTINGS.

(Continued from page 14.)

THOSE who have a greenhouse heated by hot water are to a great extent independent of external influences, and all that is necessary is to set about the work in the proper way, for failure is sure to be the result of unintelligent and badly performed operations. A frame placed at the warm end of the greenhouse over the hot-water pipes will enable the amateur to raise a quantity of plants for bedding-out, thus making the garden gay in summer, and for raising plants in spring, which grown through the summer will make the greenhouse bright at that season, besides affording plants for house-decoration.

The bed, for there must be one, is readily formed by bricking-up the sides from the floor so as to enclose the hot-water pipes. The ends must also be closed in a similar manner, so that the heat cannot escape by either the sides or ends. The width ought not to be more than 1 foot on each side of the pipe, or pipes if they are above each other, clear of the pipes to the brickwork. This will give a space of 2 feet 4 inches clear, and will need a frame 2 feet 6 inches wide to rest on the brickwork; or if the bed be against a side or end wall of the house the frame on that side may be supported by holdfasts driven into the wall, and the side walls should be carried up so that they are 6 inches on the level above the hot-water pipes. The part below the pipes may be filled in level with the bottom of the hot-water pipes solid, and the part around and above the pipes filled with coarse rubble surfaced with a layer of finer yet open material. The bed is now ready for the frame.

The frame should have sides about 6 to 8 inches deep, both sides

alike if a span, and if a lean-to the back to be a foot to 15 inches deep; or if a span roof, 1 foot to 15 inches at the ridge. This difference in height will admit of different sizes of cuttings. Inch red deal is a proper material for the sides and ends, and should be given a coat or two of creosote to preserve it from decay and fungi. The lights need not be thicker than $1\frac{1}{2}$ inch, as little woodwork being used as possible; only sufficient must be employed to insure stability. The glass should be 21 oz. sheet thirds. Cuttings require shade, of course, but it can be given when the sun is bright, and when that is not the case the more light the cuttings have the better. The lights are best hung on hinges or butts (brass being the best and cheapest in the end) either at the back or at the ridge, as the case may be, lean-to or span, which will readily allow of inspection of the cuttings. Means for regulating the ventilation are unnecessary, except such as can be readily improvised by the propagator—small pieces of board cut into small serratures, so as to form notches, are as good as anything. This thing being completed—I have been somewhat explicit, so that anyone with a little ingenuity may easily be their own carpenter, glazier, painter, and mason—we have only to provide the plunging material.

There is no question that a non-conducting, porous, moisture-holding, and slow-decomposing material is far the best. Peat or loam, as might be the staple required for growing the plants, with a large admixture of silver sand, was considered the best material for cuttings; but this is exploded. Experience has proved that what is also the best plunging material is also the most efficacious as a root-producer. The best plunging material and for rooting cuttings in is cocoa-nut fibre refuse. This is one of the many good hints for which we are indebted to Donald Beaton, and which I tried over twenty years ago. Its extensive use speaks volumes as to its value. The next best material is unquestionably sawdust, first brought to public notice by Mr. David Thomson in these pages. Either of these materials put in the frame 4 inches deep answers as a plunging material if it be considered advisable to have the cuttings inserted in pots, which is quite unnecessary for nine-tenths of the cuttings an amateur usually propagates, or greenhouse plants generally, as the cuttings inserted in the material will root quite as well—nay, better—and they can readily be lifted and potted. It must be observed that neither of the materials is intended to be put forward as the best for growing plants, hence those that do not care about potting-off can insert the cuttings singly in thumbs in the soil the plants would require when growing, with about twice as much sand as would ordinarily be employed.

If the plunging or inserting material be in a proper condition as to moisture, a gentle sprinkling will be all the water required. The frame can be kept close until the cuttings start into growth, if they are of a description that root quickly, or if there be too much moisture it can be liberated by a little ventilation; but it is far better to wipe the glass every morning than to admit air to dispel it, particularly in the daytime, when the exhausting process consequent on evaporation is at its height. A little at night is far better, especially if the plants have required water to insure their keeping fresh. Shade should only be given to prevent flagging, and will need to be more particularly attended to when the cuttings are inserted, or rather for a short time afterwards, than when they have been inserted some time. When the cuttings have rooted ventilation should be given, so as to gradually harden them, and having grown to the extent of a couple of inches their tops may be taken off and inserted as cuttings. The removal of the tops of the first lot of cuttings will cause them to branch, and, what is of more consequence, better enable them to bear the potting process. If potted when the tops are removed return them to the propagating frame, where they will sooner become established, and when started into growth again place them in a not-too-airy position of the house for a few days.

Those having a house divided into two compartments, one a greenhouse and the other a stove, can propagate the latter plants in a frame similar to that described for propagating greenhouse plants; indeed most plants will strike in a frame placed in a house in which the plants are growing, but the process will, though slower, be quite as sure as if bottom heat were employed, which, it may be observed, only facilitates the process.

But what is the amateur to do who has none of the above means of propagating plants, having only means of wintering plants in a cold frame or in the windows of his dwelling? There is no means for it in such a case than to fall back on the immemorial hotbed. It is a homely method, and with care and attention much can be accomplished.

The materials of the hotbed being collected, say some tree leaves and fresh stable litter with its droppings—three parts of the former and one of the latter—these must be well shaken together, moistened if dry, and thrown into a heap. When the materials are at a good heat, or in about a week, it should be again turned, outside to inside, again damped in the turning if there be any dryness, and with another turning and after laying a week it will have parted with any rank

steam and the heat have diffused itself through the mass. Then it can be made up into a bed to suit the frame, but extending 15 inches beyond it every way. A bed about 3 feet high will be sufficiently high, made up at the end of February, for commencing propagation early in March. The frame can be placed on. In a week the heat will be up, level any inequalities, replace the frame and put in 6 inches depth of cocoa-nut fibre refuse or sawdust. Into this the pots can be inserted about two-thirds of their depth, and with needful care in preventing damp or its opposite, extreme dryness, and shading from sun, with the needful air to expel an excess of moisture or foul exhalations, success can be insured. By the time the cuttings have rooted the bed will be cooled and the hardening process perfected by ventilation. A frame of this kind serves many useful purposes besides raising cuttings—viz., one of the best being a stock of plants from seed.—G. ABBEY.

(To be continued.)

NOTEWORTHY PLANTS.

THE "Botanical Magazine" for the present month contains portraits of the following plants:—

Decaisnea insignis (plate 6731).—A shrub from the Eastern Himalayas, found at an elevation of from 7000 to 8000 feet. In habit it much resembles a miniature Ash, with leaves borne on stalks in opposite pairs. The flowers are inconspicuous, but the ripe carpels are of a beautiful golden yellow and very attractive. With a little care at first this plant might possibly stand our winters. It is undoubtedly an acquisition.

Primula prolifera (plate 6732), probably better known under the name of *P. imperialis*, is an introduction of great value to hardy plant growers. Found at an elevation of from 4000 to 16,000 feet it is well qualified to withstand all the variations of our English climate. The leaves are exactly like those of *P. japonica*; and the flowers, which are large bright sulphur-yellow, are borne in whorls of a dozen at intervals on the flower stem. It was introduced by Anderson Henry, Esq., Edinburgh, in whose hands is the stock, which we hope will soon be distributed among his friends.

Lotus Peltorhynchus (plate 6733).—A remarkable plant from the Canary Islands. It has hitherto been exceedingly rare, but seeds have been obtained at Kew, and will soon be distributed. The flowers are very bright scarlet, borne in clusters towards the ends of the shoots, very branching, with narrow Galium-like leaves in whorls. A real acquisition amongst greenhouse plants.

Morina Coulteriana (plate 6734).—Although from a garden standpoint not to be compared to the old popular *M. longifolia*, its small, yellow, curious curved flowers make it a desirable plant where variety is in demand. The habit is much the same as *M. longifolia*, with narrower spiny leaves.

Phacelia campanularia (plate 6735).—A hardy annual, nearly allied to the much-admired *Phacelia grandiflora*. The flowers are scarcely so large, but of a much more intense blue, even rivalling our best Gentians. They are also very numerous and attractive.

ROYAL METEOROLOGICAL SOCIETY.

THE annual general meeting of this Society was held on Wednesday evening the 16th inst., at 25, Great George Street, Mr. J. K. Laughton, F.R.A.S., President, in the chair.

The Secretary read the report of the Council, which showed that the past few months mark a very important epoch in the history of the Society. In October the Council received the intimation that Her Majesty had been graciously pleased to grant the Society permission to assume the prefix "Royal." In consequence the Society has become and will henceforth be called the Royal Meteorological Society. In December the Fellows made certain alterations in the byelaws, by which the annual subscription has been increased. The report also showed that the Society is doing a great deal of practical work, not only by holding meetings and publishing the papers read at the same, but also by the establishment of a large number of observing stations, which are regularly inspected, so that the results obtained from them may be strictly uniform and comparable. The number of Fellows is 549, and of honorary members nineteen, thus making a total of 568.

The President then delivered his address, in which he referred to the experiments made by Mr. Saxon Snell, Mr. Bertram, and Mr. Hele Shaw, with the object of determining the coefficients of Biram's anemometers. As yet these can scarcely be considered quite satisfactory, for though made with the utmost care they give results differing from each other by nearly 25 per cent., and from the known truth in opposite directions. The reduction of barometric readings to sea level is another problem of great interest and importance, the solution of which is far from perfect, and as applied to the converse determination of altitudes has been pronounced by Mr. Gilbert of the U.S. Geological Survey to be beset with difficulties "so numerous and so baffling, that there is no reason to hope that they will ever be fully overcome." In many cases, too, the reduction, even if correct, implies an accumulation of air in places where no air exists; and isobars so drawn traversing mighty mountain ranges such as the Rocky Mountains or the Himalayas, or elevated plateaus such as those of central or eastern Asia, convey an impression which may easily lead to serious mistakes. The great achievement of the year is unquestionably the gathering-in of the observations taken by international agreement at nine arctic stations, in which amidst circumstances of more or less discomfort parties continued through a full period of twelve months. With one station established by the United States on the shores of Lady Franklin Bay it has been found impossible to communicate. This was established in the summer of 1881, and no trustworthy news has since been

received. Preliminary reports have been published from the English station at Fort Rae on the northern shores of the Great Slave Lake, from the German station in Cumberland Sound, from the Austrian at Jan Mayen, and from some of the others; but the principal interest attaches not to the observations taken separately, but to the collation and comparison of the whole, which may be expected to lead the way towards problems of the greatest importance to meteorology. In the present day one science is so mixed up with a number of others, and so involved in them, that it is impossible to separate them, or to define the exact limits of each. Many of the problems of meteorology belong as much to geography, or at times even to experimental physics, and an address which speaks of the progress of meteorology is perhaps apt to appear in some degree discursive. It is that the true student of Nature, whilst limiting his detailed work to one particular direction, must consider her kingdom as a grand and comprehensive whole, one and indivisible.

The following gentlemen were elected the officers and Council for the ensuing year:—*President*: Robert Henry Scott, M.A., F.R.S., F.G.S. *Vice-Presidents*: Hon. Ralph Abercromby; Edmund Douglas Archibald, M.A.; John Knox Laughton, M.A., F.R.A.S., F.R.G.S.; William Marcet, M.D., F.R.S., F.C.S. *Treasurer*: Henry Perigal, F.R.A.S. *Trustees*: Hon. Francis Albert Rollo Russell, M.A.; Stephen William Silver, F.R.G.S. *Secretaries*: George James Symons, F.R.S.; John William Tripe, M.D., M.R.C.P. *Foreign Secretary*: George Mathews Whipple, B.Sc., F.R.A.S. *Council*: William Morris Beaufort, F.R.A.S., F.R.G.S.; George Chatterton, M.A., M.Inst.C.E.; John Sanford Dyason, F.R.G.S.; William Ellis, F.R.A.S.; Charles Harding; Richard Inwards, F.R.A.S.; Baldwin Latham, M.Inst.C.E., F.G.S.; Robert John Lecky, F.R.A.S.; Edward Mawley, F.R.H.S.; Cuthbert E. Peek, M.A., F.R.G.S.; Capt. Henry Toynbee, F.R.A.S.; Charles Theodore Williams, M.A., M.D., F.R.C.P.

CULTIVATION OF DOUBLE PRIMULAS.

Few plants are so valuable as these when successfully grown. They are useful for affording flowers, cuttings for table decoration, also for greenhouse and conservatory adornment, and by judicious treatment may be had in flower for ten months of the year. The best method of propagating double Primulas is in the first place to prepare a quantity of well-decayed leaf soil passed through a fine sieve; it should be mixed with sharp sand in the proportion of one bushel of leaf soil to a peck and a half of sand; after this is done pack the compost rather tightly round the collar of the plants so as to form a kind of pyramid round each. This should be done in May or June to insure early flowers, and for succession another batch should be done a month later. The plants should be placed in a close house or pit, water being withheld from the roots, only syringing moderately to keep the compost moist. In about a month from the time of being dressed roots will be found starting from the stems of the plants. It should be mentioned that before using the compost some of the leaves should be removed with a sharp knife, leaving about half a dozen to a head. Shading must also be employed to prevent the soil getting dry, as the less the plants are watered the better.

When the roots have firm hold of the leaf soil the plants should be shaken out of the pots and divided with a knife, leaving all available new roots with each crown. Transfer the young plants into 60-size pots, which should be placed into a close pit close to the glass, and if a little bottom heat be at command so much the better. For instance, an old Melon or Cucumber frame will answer admirably for this purpose. Shading must be again attended to, gradually lessening it as the plants become established, which can be seen by turning a plant or two carefully out of the pot, and then they should be shaded only when the sun is very strong. Repot them in about half and half leaf soil as finely sifted as before, and very light fibry loam with plenty of sand and careful drainage.

When the plants are well rooted, which will be about a month from the time of potting, they will require shifting to 48-size pots, which are large enough however luxuriant the plants may be. The compost employed this time should be three-fourths turfy loam and one-fourth well-decomposed cow manure, the plants now being placed in a pit without any bottom heat.

The second and third batches should be placed in a house slightly shaded if the situation requires it, and kept close for a few days, then gradually inure them to the light, as after October they will require full exposure to insure good and strong foliage and flowers. The first potted batch will by this time be showing a number of flowers, and should be removed to alight structure or placed on shelves where a small quantity is grown. The temperature of the house during the winter months must be as near 55° by day as possible, or rising to 60° with sun heat and falling to 50° at night. After the pots are filled with roots a little soot water may be given once a week with advantage, also a little Clay's Fertiliser once a month. The lower leaves when showing signs of decay may be cut in quite close either with a small knife or a pair of Grape scissors, removing a good quantity

whether decayed or not where flower only is required, as this will encourage and prolong their blooming.

After the first batch has been in flower about a month they will require a rest for a time. In three weeks, however, they will begin to flower again, but the second batch will take their place in the interval, so that by this means the cultivator may have a continuation of useful flowers till July. Shading must again be provided when the bright days of spring come, as the flowers soon becomes pinky, which deprives them of their value when pure white flowers are in request. Careful watering is essential throughout the season.—J. PITHERS, *Summerhill*.

ERYNGIUMS.

ALTHOUGH umbelliferous plants generally have little floral beauty to recommend them to the general cultivator, yet a few

Fig. 11.—*Eryngium maritimum*.

compare very favourably with many of our favourite garden plants in handsome foliage and general ornamental character. Eryngiums, or Eringos as they are more commonly called, rank among the most striking of these; the bright and varied colours presented by their involucre, and also by their foliage, render them very attractive and desirable. They are said, however, by some not very hopeful growers to be too tender for our climate and to succumb during winter, a charge which may hold good when the season has been excessively damp; an extreme to which, although we are unfortunately liable, is hardly sufficient excuse to account for their scarcity in cultivation. The fault lies more, I think, in the fact that we are not so persistent in our efforts to succeed as we ought to be; too ready to throw it up as useless, after one, or at the most two, unsuccessful attempts to establish them. I find that in our average winter these plants require no protection whatever, and such as *E. pandanifolium*, *E. bromeliæfolium*, *E. Lasseauxii*, *E. paniculatum*,

and *E. giganteum*, which are considered the most tender in cultivation, prove excellent for the rockwork, even in the most exposed situations, where their graceful spiny-edged foliage lend quite a subtropical character to it, even in midwinter, and more especially when tastefully arranged and dotted about for effect. That much requires to be done in this way before we can claim or even think of perfection in the art of rockwork ornamentation is obvious, not only from the desolate and neglected state most of them present in the winter season, but also in the careless distribution and arrangement of the plants.

The Sea Holly (fig. 11), as *E. maritimum* is not inaptly termed, is one of the most striking of our native plants, and has very beautiful silvery spiny foliage, which contrasts very agreeably with the steel-blue flowers. It is easily grown either on a rockery or in a light well-drained border.

A few of the other species not favoured with such striking foliage as the above compensate for this defect in the varied beauty of their involucres. Among them *E. amethystinum*, syn. *E. azureum* and *E. cœruleum*, *E. Andersonii*, *E. campestre*, *E. Bourgati*, and *E. dichotomum* are all worthy of cultivation, and should find a place in every garden where room can be spared for their full development.

As their roots are easily injured in a damp undrained position a rockery should be chosen as a site, but where that is not available its place can be, to a great extent, supplied in the border by the free use of stones about the roots when planting, always choosing the most elevated position. This is not so unsightly, and serves its purpose better than the old-fashioned mound of earth so much resorted to long ago.

Eringos are rather difficult to propagate by division, owing to most of them having large tuber-like roots, and are much easier managed from seed, which should be sown as soon as ripe in pots and placed in a little heat. Gradually harden the seedlings and as soon as they are ready to handle place them in large thumb pots.—M. S.

PEACH TREES CASTING THEIR BUDS.

CAN any readers of the Journal say from experience if the constant use of spring water would be likely to cause Peach trees to cast their buds? The trees in question are six in number, and were planted three years ago in an inside border, all having done well. Copious supplies of water were needed, and having little reserve for soft water, we were driven to use the water above mentioned, which we warmed to the required temperature. All appeared satisfactory, and a good crop of fruit was anticipated up to about a month ago, when the buds began to drop out, and have continued to do so to a serious extent, though the house is fully ventilated. The house is a lean-to facing south. Three trees are planted along the front, two supernumeraries in the centre, and one at the end; they are successional varieties, but all are casting their buds alike, not only fruit buds, but in many instances wood buds as well. I find on examination that these are black in the centre, and appear to have been dead some time. What can be the cause?—ALPHA.

GARDENS ABOUT BRISTOL.

BRENTREY HOUSE.

THESE gardens have been for some years under the charge of Mr. Gibson, and give unmistakeable evidence of the skill and energy of this intelligent gardener. The whole place is exceedingly well kept, and nothing but the best of everything grown, overcrowding being carefully avoided, while cleanliness ruled everywhere. Most noteworthy as being most uncommon was a house devoted principally to Dipladenias. These completely covered the roof, and strikingly beautiful were the grandly flowered plants of the richly coloured *D. Brearleyana*; and in contrast with these were several seedlings of various shades of colour, the most distinct having large blooms of a lovely pale pink hue; and another with medium-sized blooms of a rich crimson and shaded purple, was also good and distinct, especially in its sturdy habit of growth and smooth green leaves. Several of the plants annually perfect a few of their curiously formed seed pods, and these seeds, if sown when ripe and before they become hard and dry, germinate readily in a brisk bottom heat. Mr. Gibson's seedlings vary considerably in habit and colours, some assuming a more shrubby habit than is common to the species; others, again, are singularly precocious, as they commence flowering when only in 4-inch pots. Mr. Gibson attributes much of his success with Dipladenias to the pains taken with the potting and watering. Large shifts are avoided, and the compost is composed entirely of roughly broken fibrous peat of the best quality, to this being added a liberal quantity of charcoal, crocks, and silver sand. Overwatering or anything approaching stagnation at the root soon proves fatal to these lovely climbers. They require to be trained thinly over the roof, and a rather high temperature, say from 65° to 70° by night to 75° to 80° by day, and still higher in warm weather, a proportionately moist atmosphere being also maintained. They must be kept scrupulously clean, mealy bug especially quickly overrunning them. In another three-quarter span-roofed plant stove the wall and back part of the roof was beautifully draped with a mixture of *Allamanda Hendersonii*, *Cissus discolor*, and *Dipladenias amabile* and *boliviensis*. The two former were

planted in a narrow border filled with good loamy soil, the *Dipladenias* being in pots, and the rich foliage of the *Cissus* intermingled with the flowering climbers presented the prettiest sight I have seen for some time. In an adjoining plant stove the back wall was principally covered with *Poinsettia pulcherrima*, and these planted in a narrow border composed of good loam were growing vigorously, and must subsequently have produced a number of fine showy whorls. They are freely cut for decorative purposes, and the season I was informed is a remarkably long one. *Sephanotis floribunda* are well done at Brentrey. Several experiments have been made with plants obtained from noted shy-blooming plants; but so floriferous do all alike prove, that Mr. Gibson does not agree with myself and others who are inclined to think there are some varieties much more floriferous than others.

Orchids are also well grown, the various sorts being very strong, and are said to bloom exceptionally well. *Phalaenopsis amabile*, *Cattleya Harrisonii*, and *Odontoglossum grande* were the most noteworthy at the time of my visit, and certainly bore out what had been said of the flowering qualities of the Orchids generally. Gardenias, Crotons, Dracenas, Euphorbias, Pandanus, Pterocarpus, Eucharises, and various Ferns were all in a very creditable condition, and very pretty were two baskets filled respectively with *Hoya bella* and *Æschynanthus splendens*. In a cooler house a strong plant of *Thunbergia Harrisii* was carrying large quantities of its charming pale blue flowers, and the wonder is that so few try to grow this valuable climber. At Brentrey it grows vigorously; and trained over the roof, for which style only is it adapted only to the brittle nature of the growths, it produces during the autumn a profusion of racemes of bloom which find great favour with the ladies. Near the end of September the plants are carefully removed to a house where an ordinary stove temperature is maintained, this serving to greatly prolong the display. They require but little root room, the strongest plant at Brentrey having been in a 12-inch pot for three years, but has had the surface soil and some roots removed, and more good soil given by way of top-dressing. A good peaty soil appears to suit them, and in the growing and flowering season water varied with liquid manure is frequently and liberally supplied them.

Mr. Gibson is a very successful Grape-grower, and had Madresfield Court, Muscat of Alexandria, and other popular sorts in excellent condition. The borders are inside and out, and the former rightly receive more water and liquid manure throughout the year than the majority of authorities appear to think necessary. Melons and Cucumbers are also well grown, and a few Pine Apples are annually fruited. The conservatory adjoining the residences was attractively arranged, and the kitchen garden is equally well managed. Altogether Mrs. Miller, the proprietress of this place, has every reason to be well satisfied with it.—W. IGGULDEN.

HARDY FRUIT GARDEN.

PLANTING FOR PROFIT.—Where to Plant.—A sunny slope facing the south or south-west, well sheltered from the north and east, is undoubtedly the best position; but such favoured spots are rare, and planting on the level or in open and exposed positions has more frequently to be done. A belt of trees planted at the same time around the fruit garden or orchard is good for shelter, but a thick hedge of *Thuja Lobbi* is better, for it grows faster than any fruit tree, and its dense growth is an effectual check to wind. By all means plant a tree belt, but plant also a *Thuja* hedge in front of it, and have *Thuja* hedges also intersecting the orchard, so as to break the sweeping wind among the trees, for depend upon it if we had such hedges at intervals of 60 feet or upwards among our fruit trees the blossoms would be far less subject to injury from cold wind in spring.

What to Plant.—Fruit which comes early and abundantly upon the trees, ripens early or keeps good late, combined with a healthy sturdy growth of tree or bush in all fertile soil, is what we require, and we must avoid all fanciful or speculative planting. Of Apples no dessert sort affords an earlier or more steady profit than Margil. Grafted upon the Paradise stock it makes compact little bushes about 6 feet high and of the same diameter, and every branch is almost invariably crowded with fruit from top to bottom. Nine feet apart is sufficient for such bushes, so that an imperial acre will contain 537. Taking the crop at that number of bushels, at 4s. per bushel, we have the handsome sum of £107 8s. per acre. Halve it, and we have still the by no means despicable sum of £53 14s. We have had at the same time sturdy little bushes of Margil bearing such a crop, and huge standards of Fearn's Pippin, each laden with twenty bushels of its handsome rosy fruit. If the standards would always yield such a crop we should find them most profitable, but they do not, and the bushes do, therefore we are bound to recommend them. Plant also extensively of Apples Duchess of Oldenburgh, Keswick Codlin, Mank's Codlin, Adam's Pearmain, Stirling Castle, and Warner's King, for all are of sterling merit for profitable culture. Among Pears the same may be said of Williams' Bon Chrétien, Autumn Bergamot, Beurré Clairgeau, and Comte de Flandre. Of Plums there is none like Early Rivers. Plant pyramids of it 10 feet apart, or 435 to the acre, and you will soon be rewarded with heavy crops of fine fruit ripe and in

the market before any other Plum is ready. Victoria follows it, and is well worthy of moderate culture, its fruit being large and abundant. Cluster Damson, May Duke Cherry, Pearson's Prolific Nut, Warrington Gooseberry, Prince of Wales Raspberry, and Black Naples Currant are also all profitable fruits, the last one being undoubtedly the most profitable of all in suitable soil and under good culture.

When to Plant.—At once without delay, or the trees will not make good growth this year. Never have we known a more favourable winter for planting from November onwards.

FRUIT FORCING.

VINES.—*Early Houses.*—Disbudding and tying-down Vines in early houses must have timely attention; removing all surplus bunches as soon as the most promising can be decided upon, as to leave any surplus bunches only needlessly weakens those that must ultimately remain. Thin the bunches of Hamburgs and all early varieties (excepting Sweetwaters) as soon as the berries are set, but those that do not set freely should not be thinned until the properly fertilised berries can be distinguished by their taking the lead in swelling. Any shy-setting varieties, such as Muscats, should be fertilised with Black Hamburg pollen. When Muscats are in flower keep the house drier and a few degrees warmer, affording circulation of dry warm air on all favourable occasions. For Hamburgs a night temperature of 60° to 65° will suffice, with 5° rise by day in dull weather, and 10° to 15° with sun heat. Muscats should, when in flower, have a night temperature of 65° to 70°, 75° by day in dull weather, and 80° to 90° with sun heat. As the roots will now be active, inside borders should have a good soaking of water as soon as the berries are fairly set, giving it at a temperature of 80°, which will from the warmth prove a great incentive of root-action. If the outside border is covered with fermenting materials and the temperature falls below 80°, add a few fresh leaves and stable litter, replacing the shutters, but keeping them quite clear of the fermenting materials.

Succession Houses.—Vines treated as advised in former calendars will soon be starting; but continue to syringe twice a day and turn the fermenting materials frequently, alike for liberating moisture and ammonia. If there be no fermenting materials use weak liquid manure for damping the floor and borders; but it must not be used on the Vines, or it will accelerate the production of aerial roots, especially from the rods of Vines somewhat aged, or young ones either if there be little activity at the roots proper. The temperature should range at 55° or a little higher on mild nights, and 60° to 65° in the daytime, allowing an advance from sun heat to 70° or 75°, but with a free circulation of air, especially now that the weather is so mild. Syringing should be discontinued as soon as the bunches are distinguishable, yet a suitable atmosphere must be maintained by damping the floor and walls. Maintain a supply of manure in the reserve ground, so that it may be introduced into the houses in a sweetened condition as occasion requires—small quantities at a time and often.

Early Vines in Pots.—Complete the thinning of these as soon as practicable, and be very careful not to overcrop them, as this is one of the most fatal evils of Vine culture. Afford tepid weak liquid manure freely whenever needed, pouring it on the material placed around the pots after the roots have passed into it, keeping up the bottom heat to 75° by turning and adding to the fermenting materials as necessary. At night 65° is a sufficiently high temperature and 5° less on cold nights, and 70° to 75° by day, admitting a little air at 75°, allowing an advance of 10° to 15° from sun heat, and close early or at 80°.

Raising Canes for Fruiting.—There must not be any further delay in getting cut-backs and eyes into heat which are intended for growing into fruiting canes. When the former have pushed about a couple of inches they should be shaken out and potted in new compost, using 7-inch pots or larger according to the strength of the roots, and place them over bottom heat near the glass.

Grape Room.—Examine the whole of the fruit at least twice a week, removing all decayed berries, and if the Grapes show any disposition to mould or other decay light gentle fires early on fine dry mornings and ventilate freely. Ventilate on all fine days, keeping the room quite close in damp weather.

FIGS.—*Early fruited Trees in Pots.*—These have had the advantage of unusually mild weather, and have made great progress without our having to resort much to fire heat. The trees have had the benefit of a bed of fermenting materials; these should be added to as necessary, so as to keep the heat steady about the pots at 70° to 75°. Stopping must be attended to, and where trees are aged close stopping will be needed, pinching the young growths at the fifth or sixth leaf; but where the trees are extending no more stopping need be practised than is necessary to form symmetrical trees, and on these the finest fruit will be produced. When the trees have grown to the extent above indicated the night temperature should range from 55° to 60°; 65° to 70° by day by artificial means, and 10° more with a bright sun. Commence ventilating a little at 70°, increasing it with the sun's power, but be careful not to admit cold draughts of air directly upon the foliage. Syringe the trees and walls copiously twice a day, as red spider will assuredly appear if there be any neglect in this. Give liberal supplies of tepid liquid manure as necessary, for if there be any deficiency so as to cause a check the effect on the first crop of fruit will be fatal.

Trees Planted Out.—The treatment advised for early houses will apply to successions, whether the trees are planted out or in pots. In the case of those planted out the borders should be well mulched with decayed manure, and supplied with tepid water repeatedly until every particle is thoroughly moistened down to the drainage.

Late Houses.—The trees must be thoroughly cleaned, also the houses, and everything prepared for starting. Every particle of the wood must be thoroughly washed with soapy water, 6 ozs. to a gallon, and afterwards dress with some approved insecticide, observing great care in dressing the young wood, as the embryo fruit is easily injured. The old mulching should be removed and fresh supplied.

Raising Young Trees.—If it be desired to increase the stock of young trees, cuttings or eyes inserted now and plunged in bottom heat will make good plants for potting at the end of the season of growth. For making trees with clean straight single stems of any required eyes are the best, and they do not give any trouble from underground suckers. Brown Turkey and Negro Largo with White Marseilles are fine for any purpose.

Melons.—If sown as advised in a previous calendar, and attended to as advised, they will now be in rough leaf and will need a shift into 5-inch pots, and be again plunged in the pit close to the glass, and a small stick placed to each of those intended for training to trellis and secured thereto, whilst those intended for pits or frames should be stopped at the second rough leaf, and may be planted out as soon as the planting medium is prepared. Melons delight in a stiff loamy soil with an admixture of old lime rubbish or charcoal to keep the soil porous. A ridge or hillock should be formed along the centre of the pit or frame, or in the middle of each light about 10 inches deep, the soil being made firm, and should be in a moist condition, so as to lessen the necessity for watering in the early stages of growth. One plant is ample in a light, unless the lights are above the ordinary size, when two plants may be placed in each, one to be trained to the front and the other to the back. See that they are properly moist before turning them out, and make the soil firm about the plants. A little soot in a circle about the plants will save them from the ravages of slugs. If the bottom heat is obtained from fermenting materials the plants should not be placed out until the temperature has fallen to 90°, whilst if from hot-water pipes keep it steady at 80°. The top heat should be 65° at night, 70° to 75° by day, with a rise of 10° to 15° from sun heat. Keep up a good heap of fermenting materials in a proper state of fermentation for making up new beds, or prompt application to beds or lining when such are necessary. Sow seed for succession.

Strawberries in Pots.—Mild weather has greatly assisted the progress of the plants. Very little fire heat is necessary for newly started plants, which is of great benefit up to the time the fruit is fairly set and swelling. See that there is no trace of mildew, and ventilate promptly even in dull weather if the air be mild. The air of the house should be kept comparatively dry when the plants are in flower, and examine the blossoms when the sun has been out some time; dusting them with a brush of camel's hair to assist fertilisation. When set and swelling raise the temperature to 60° or 65° by artificial means, and 10° to 15° from sun heat, and close early with plenty of moisture in the house. This will cause the fruit to swell quickly to a good size. Thin the fruits, removing all that are deformed as well as the small—a few good-sized fruit being better than thrice the number of small. The plants must never want for water. Examine them twice daily, and give liquid manure two or three times a week in a tepid state. When the fruit commences ripening keep a drier atmosphere and a rather drier condition of the soil. Plants stored in pits or frames should be looked over frequently and given water when there is the least indication of dryness. Admit air abundantly.

PLANT HOUSES.

Aerides, Vandas, and Saccolabiums.—These plants grow well in baskets suspended from the roof of the stove, in fact no better position can be accorded them. Many grow these plants in pots in the warmest house; but where room is limited and the flowers are required to be cut they are best grown in baskets. Even in this condition they can be arranged amongst other plants while in flower if thought desirable. These plants may now without further delay be examined and given larger baskets if they require them, or may have the material surrounding them removed and fresh supplied. If the roots of any of these kinds cling tenaciously to the old baskets, remove only such as can be done without injury to their roots. In preference to breaking the roots by removing them from the baskets in which they are growing place them as they are into others of a larger size. The whole of the potting material should be removed from amongst their roots and fresh given, for these plants dislike decomposed matter about their roots, and in such a state will not long remain healthy. The baskets should be liberally drained with broken pots and lumps of charcoal, the remaining portions being filled with living sphagnum moss only. While growing these plants require liberal supplies of water, and the moss in one season becomes sufficiently decomposed for removal. We remove the whole carefully and wash out the small particles by pouring water into the baskets. Amongst the moss crocks and charcoal may with advantage be used. These plants delight in sending their roots through the baskets into the moist atmosphere of the house.

Oncidiums.—The majority of these that require heat do well in the stove in baskets and while at rest can be removed to cooler quarters. Such species as *O. flexuosum*, *O. lanceanum*, and others that have commenced making fresh roots may be attended to. In removing them to larger baskets, exercise the same care as advised above, and do not injure their roots more than possible. Many of these plants delight in sending their roots outside the baskets, and with such varieties no attempt should be made to place them inside; on the contrary, allow them to grow as naturally as possible. If the whole of the compost is removed every second year it will be found sufficient. They should, however, be examined every year, and a

little fresh peat moss or charcoal added as the case may be. This is the mixture we use for these plants, allowing the former to predominate; but all the small particles should be shaken out and only the fibre used. Charcoal must be used in lumps freely. In renewing the compost where required the roots clinging to the crocks or charcoal need not be disturbed, as the old peat and moss may with care be removed.

Phalænopses.—Many of our plants suspended in the stove have already commenced root-growth, and these will be seen to at once. Small plants of these that have not hitherto been in baskets are given 6-inch baskets to commence with. These are nearly filled with crocks and charcoal, which are covered with living moss elevated in the centre, and then the roots well covered with the same material. The whole of the moss is picked carefully from amongst the roots annually and fresh employed. Care must be taken that the moss has been in the house in which the plants are growing to become warm before being used, or very serious results may follow. The plants after this operation must be kept well syringed to encourage the moss to grow, and if this is accomplished they will receive the moisture they require. If woodlice have become established in the baskets destroy every one if possible when removing the moss from amongst their roots, for no better opportunity will ever occur. These insects, if allowed to exist in the baskets of these plants, soon destroy the foliage when young and tender, and are also very fond of the flower spikes when in the same condition.

THE BEE-KEEPER.

SYRIAN BEES.

I WILL give my experience with Syrian bees, and as I do not rear queens to sell I have "no axe to grind." When I first heard of the Syrian bees I was anxious to try them, so I sent to Mr. Jones for two queens, which I received in July, 1881, and, as it was too late in the season to test them thoroughly, I concluded to keep them until I was satisfied whether they were inferior or superior to other races of bees.

In the fall of 1881, when I prepared them for winter, they were stronger in number than the rest of my bees. They stood the winter well, and in the spring of 1882 they were more populous than the Italians and albinos; so I thought that I would rear a few queens for my own use, and I succeeded in rearing some very fine queens, and as I did not put on any boxes in 1882 I did not get any surplus honey; but when I prepared them for winter in the fall of 1882 I found nearly every colony had twice as much honey as they needed to winter on, having the brood-chamber full, with the exception of two or three combs, which was about half full of brood.

The winter of 1882-83 was hard on bees in this part of the country, but my Syrians came through in good condition; they wintered better than the rest of my bees, excepting the Cyprians, which I had one and a quarter mile from my home apiary.

Nearly all the rest of my bees (Italians, albinos, and hybrids) were weak and in a deplorable condition, so I had to take frames of hatching brood from the Syrians to build up weak colonies, and when the combs were full of brood, and the young bees commenced to gnaw through, I took them out and exchanged them with the weak colonies the second time.

After taking all the brood out twice, it did not seem to affect them at all; and, by the time white Clover was in bloom, they were stronger than the Italians and albinos, and they commenced to work in the sections two weeks before the Italians (I did not take any brood from the Italians). The Syrians cast larger swarms, besides gathering more surplus honey than the Italians ever did for me.

The young colonies filled eight-frame Langstroth hives, and stored more honey in the sections than did the old colonies of Italians and hybrids, while the albinos and hybrids only filled the brood-chamber, and only gathered enough honey to winter on this fall. When I prepared them for winter they all had plenty of honey to carry them through safely, and more.

I find the Syrians splendid honey-gatherers; they work early and late; they carry heavy loads of honey, and there are lots of them. And yet some say they are no good.

The albino bees are not as good as the Italians. I have had them on trial for three or four years, and I know whereof I speak. I never got as much honey from them during all this time as I did this year from one colony of Syrians. I have "weighed them in the balance" and "they are found wanting." They had their day, and must step down and out. I will keep one or two colonies of them just to look at.

One writer says that he would like to see the man "that can tell the difference between the Italians, Syrians, and Cyprians." I find no difficulty in telling one from the other, and even queens fertilised by Cyprian drones produce bees which are readily known from pure Syrians. The general colour, markings, and movement of these bees, to say nothing of their working qualities, are sufficient to enable one to distinguish the races readily, but there are also other points in which they differ.

The bees present a decidedly grey colour, though the abdomen has a ringed appearance. The ground colour is a greyish black; the body, before the fuzz is worn off, being very light; the grey-coloured fuzz is very thick on the thorax, and the latter half on each segment of the abdomen, especially those after the yellow bands, are thickly set with

light-coloured fuzz, giving them a striking appearance. The three yellow bands are very prominent and yellow.

The shield between the wings is not as prominent as with the Cyprians, though still visible. The Syrian drones are very fine, large, and vigorous, and have an exceedingly thick coat of whitish and blue-tinged "fuzz" over the greater part of the thorax, especially on the sides, and a very noticeable amount on the abdomen. In proportion to their bodies, I think their wings are somewhat larger than those of the Italians or Cyprians.

The Syrian queens are wonderfully prolific, laying an incredible number of eggs in a season, and the bees build less drone comb than the blacks or Italians; they protect their stores against robbers with such determination that they often catch the robbers on the wing around the hive, and punish them before they even get time to alight; in fact, they are robber-proof.

They are swift on the wing, and no race of bees will fly more rapidly or further (when necessary) in search of honey than will the Syrians. They have been known to fly six and a half miles to obtain pasturage. I have seen my Syrians two and a half miles from my apiary; how much further they went I am unable to say. As honey-gatherers they are not excelled.

The Syrians winter better than the Italians, come out better in the spring, and do not dwindle so badly. Everything considered, I regard the Syrian bees as the most superior race ever imported into this country, and that, when they have been subjected to the same careful selection and breeding as have the Italians, they will command more prominence than have the Italians. I would most emphatically affirm that the Syrians have a larger number of the necessary qualities than any other race or strain of bees. I will admit that I am using strong language, but my experience with this race, regarding queen-breeding, honey-gathering, and wintering, fully warrant me in making the statement. I am not prejudiced against any race of bees, and the above is an honest description of the Syrians as I see them.—L. A. LOWMASTER (in *American Bee Journal*).

TO CORRESPONDENTS

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (X., Loughall).—You will find all the information required in the "Rose Garden," by Mr. W. Paul, published by Kent & Co., 23, Paternoster Row, London, price 7s. 6d. (W. H.).—Your question is so ambiguous that we cannot tell what you require. Do you need a book giving the botanical characters of British or general plants, or do you desire one that will enable you to describe plants by botanical terms? (A. M.).—The first two books you name were, we think, published by Messrs. Groombridge & Son: we do not know the price, but they can be obtained through a bookseller. The other work we suspect has long been out of print.

Garden Implements (Jay).—As we have repeatedly stated, it is contrary to our rule to recommend any implements, seeds, or firms as the "best." We can do nothing so invidious. You can obtain what you want in the town from which you write.

Rose Leaves Withering (Nemo).—A serious attack of mildew is quite sufficient to cause the discoloration of the leaves, some of those you have sent being covered with the parasite. The leaves further indicate that the plants are destitute of vigour, and probably either the roots are defective or

the soil unsuitable. Give fresh soil if needed, continue the use of sulphur, ventilate the house judiciously, and with brighter weather your Roses may be expected to improve.

Holly Leaves Falling (*J. C., Frodsham*).—In a garden that we recently visited the gardener confidently attributed the defoliation of the Hollies to the salt that was conveyed in the boisterous gale of some two months ago. He stated that salt could be scraped off the windows of his cottage and the leaves of the evergreens, and the latter commenced casting their foliage soon afterwards. The situation is twice the distance from the sea of that from which you write. This may not be the origin of the evil in your case, but the matter is worth your consideration.

Propagating Lapagerias (*H. W.*).—These plants are propagated by pegging the stems in a bed of peat and sand at a sufficient depth that about the half of each leaf appears above the surface in a vertical position. The bed being kept moist roots will be emitted from most of the joints, and the growth from each leaf axil will form a plant. It is not necessary to notch the stems.

Pinching Peach Tree Shoots (*Idem*).—We practised the plan long before the work to which you allude was published, and found it answer well, affording abundant crops of good fruit. As a rule, however, this was not quite so large as when young wood was retained, and regular and systematic attention is requisite for success. First try a modification of the plan by pinching a few shoots instead of disbudding so severely. This combination system answers admirably when intelligently conducted, as we feel sure it will be in your hands.

Building Flues and Chimneys (*D. M.*).—Your letter is practically unanswerable—that is to say, it cannot be answered usefully, as the price of such work varies with the differing price of materials and labour in different districts. In no way can you ascertain the cost so nearly as by stating the particulars to local tradesmen, and ask them to supply estimates for completing the work.

Trees on Tarred Fence (*E. M.*).—We have grown Pears against a tarred fence for years with the most satisfactory results, the boards being perfectly dry before the trees were planted. We do not apprehend any danger whatever in your case, the tar having been applied last summer. If any persons can adduce authenticated instances of failure under the circumstances indicated we will record them.

Disbudding Vines (*A Young Beginner*).—We do not approve of denuding the lower part of the rods—that is, the part from the ground to the base of the rafters—of buds, as by permitting the laterals to extend we promote the thickening of the stem; and if the stems are contracted, as we often see them, the sap vessels are contracted also. Unless the joints are very short and the eyes or buds are less than 6 inches apart we allow them to grow, at least until they meet across the space between the Vines. This strengthens the stem, and the leading cane grows as freely as if the side growths were rubbed off. If closer together than the distance indicated every alternate bud may be removed, and the foliage on the laterals that will then extend will develop the better. If the Vines are very strong one bunch on each may be permissible, not otherwise.

Liquid Manure for Pelargoniums (*A. B.*).—As you have used Clay's fertiliser in potting you must be careful in the use of liquid manure, or you may have far more foliage than flowers. That manure is excellent as a top-dressing and watered-in for Pelargoniums, and is largely used in that way by the best growers. Clear soot water is good for imparting colour to the foliage and flowers. So long as the foliage is of a deep green colour liquid manure will not be needed.

Carpet-bedding Designs (*W. P.*).—We are not aware that such a variety of designs can be found as in the back numbers of this Journal. Several, however, are included in the "Parks and Gardens of London," published at this office, price 5s., post free 5s. 6d. The work also contains instructions for raising most of the plants that are employed in carpet bedding. Mr. Graham, Hampton Court, prepared a useful manual on this subject, but we do not know whether copies are still to be had.

Peas for Small Garden (*Willing to Learn*).—As an early variety sow William the First; to succeed it Gladiator, Marvel, Maclean's Best of All, and Sturdy, all of which are excellent for successional sowing, and all are abundant producers. Very little economy results from sowing cheaper kinds, which, however good for market purposes, are not appreciated by those of refined taste. You are acting wisely in seeking to improve your clay soil by burning the subsoil. The Peas are all of medium height.

Rabbits' Dung as Manure (*Idem*).—Why should not the dung of the rabbit be as good manure as that of other herbivorous animals? We know the prejudice that existed against it among agriculturists from the fact that these animals are very injurious to their interests, and from the grass not growing strongly about their burrows, which is attributed to the baneful influence of their dung, but is really a consequence of being closely cropped. Remove the rabbits, and the grass or other crops will grow much more luxuriantly there than in any other part of the land adjoining. It will be useful in a garden for any description of crop, and would be best kept under cover; indeed all manures are, as they then have not much of the fertilising matter washed out by rains, as is the case when they are exposed.

Aphis on Auricula Roots (*J. Luck*).—Unless the plants were very seriously affected we should hesitate to shake them out now. Try the effects of paraffin on a plant or two and note the results. Mixed at the rate of an ounce to the gallon of water we feel confident it would not injure the plants, while it would check, if not destroy, the insects. Mr. Llewellyn has stated the plants seem to like a little paraffin rather than otherwise. Moderately used it no doubt acts as a manure, but an excess is dangerous. Mr. Thomson of Drumlanrig has found that, mixed at the rate of two ounces per gallon, and applied to Zonal Pelargoniums, did not do them the slightest injury; and we have used it similarly to Lettuces, which "seemed to like it," while the aphides on the roots were destroyed. The oil can only be incorporated with the water by violent and constant agitation. We are strongly of opinion that water may be given so hot as to destroy the aphis without doing any injury to the roots of Auriculas, and if we had any plants infested we should try the hot-water remedy, commencing at a

temperature of 150°. Will you try it with a plant or two and let us know the results? The average value of an acre of well-grown Black Currants is probably about £40.

Preserving Flower Sticks (*W.*).—As the paint would perhaps cost a shilling or two, and therefore be too expensive, you might try paraffin. It is a good wood-preserver, but the stakes would not have such a neat appearance as if covered with green paint. If not dressed with anything the wood would last much longer than the points of the sticks inserted in the soil if these were not charred or creosoted: and this should be done to a part that would be fully an inch above the surface of the earth, as it is just at the surface where decay is most rapid, and not deep in the soil.

Top-dressing and Pruning Vines (*Zeno*).—No top-dressings in such a narrow border as yours would equal a covering 5 or 6 inches thick of rich farm-yard manure. Failing this, remove the surface soil if you can do so without injuring the roots, and add 3 or 4 inches of good fresh loam; then as the Vines need support give them liquid manure. This may consist of sewage and urine diluted with five or six times its volume of water, with soot and guano water occasionally—a change always being beneficial. Guano is good as a top-dressing sprinkled on the surface at the rate of an ounce to the square yard occasionally; so is superphosphate of lime, two ounces per square yard. Clay's fertiliser is good used the same as guano, and Thomson's Vine manure excellent. Apply what is the most convenient, and keep the border moist from top to bottom. You have erred in deferring the pruning so long, and if your Vines are strong and healthy they may bleed excessively, as especially if Thomson's styptic or painter's knotting be not applied before the sap commences to move. Instead of pruning when the Vines are starting we prefer disbudding—removing the buds from that portion of the laterals usually cut off, and the laterals themselves after the growths from the base have developed their foliage. Read Mr. Iggulden's article on this subject in our issue of December 20th, last volume.

Planting Vines (*F. J.*).—A good time for planting Vines is when they have fairly started into growth—that is, have produced shoots 1 or 2 inches long; but they will succeed if planted when the buds are distinctly swelling, and protrude through thin scaly covering. This would perhaps be the safest guide for you to follow as you are not an expert in the work. The Vines must be obtained when the buds are quite dormant, or they would almost certainly be dislocated in transit. The Black Hamburgh is the most useful Grape for amateurs. The Black Alicante is later, free and showy, but the fruit is not of high quality. Answers to your other questions must be deferred, but a reply will be given in ample time to be of service.

Temperature for Cucumbers (*S. F.*).—You ask "If it is of any use trying to grow Cucumbers in a house in which over 55° at night cannot be maintained, increasing to 80° in the day with sun heat?" We have never seen a house exactly of the kind indicated. If you mean that you cannot maintain a night temperature of over 55° at this period of the year we fail to see that you can insure an increase to 80° with sun; while in summer, when you can insure the day temperature indicated, a night temperature exceeding 55° can be easily maintained, often for weeks, with an occasional interruption when the weather happens to be unusually cold. It is not much use your trying to raise Cucumber plants now in your house, but if you can maintain a minimum night temperature of 50° in January you will have no difficulty in increasing it as the season advances to the proper degree for growing Cucumbers. We have never had better crops nor finer fruit than from a house in which no fire heat whatever was employed, but planting was not done until June, and then the plants were very strong, having been raised in a frame. They were 18 inches high, with stems as thick as your finger, and proportionally stout foliage, the 6-inch pots being filled, but not crowded, with active roots. They were planted in turfy loam placed on a bed of fermenting material 3 feet high, and the growths trained up the roof. At that period of the year the weather was so warm that there was no difficulty during bright days of maintaining a temperature of 90°, and with a moist atmosphere the plants grew with great freedom, and by closing the house when possibly at from 95° to 100°, with much moisture, a night temperature of 65° was frequently maintained; but even if it fell to 55°, and now and then even lower, such vigorous plants received no appreciable check, but only a temporary rest, and they continued fruiting till October in the most satisfactory manner. Thus you will perceive the question of growing Cucumbers in what is a cool house now resolves itself into a question of judgment and management—waiting until the house is naturally warmer, then cultivating the plants well. Any house in which a night temperature of 45° can be maintained in winter may with the greatest ease be converted into a stove in summer by judicious ventilation; and if the requisite light and moisture are provided, Cucumbers may be grown in the structure as well as any other stove plants.

Zonal Pelargoniums not Flowering (*S. F.*).—In the first place your plants were pinched too late, and in the second they had not nearly sufficient light, arranged so far from the glass, and placed in the house, no doubt, before the leaves were off the Vines. Young plants grown generously during the summer in the open air so long as the weather remains favourable, then given the shelter of frames towards the autumn, will flower with great freedom in winter in a very light house with a temperature ranging between 50° and 60°. The end of July is late enough for topping the shoots, but the flower stems should be pinched off as they appear until late autumn. By pinching the shoots in September only small growths can result, and these never produce a succession of fine trusses. Some varieties flower much better than others during the winter, and at least one of those you name is bright and useful during the dull months of the year. We allude to Vesuvius, but it fails when the plants are not well prepared and then placed in an unsuitable house. A position under Vines is not suitable, nor can the plants be expected to succeed so far from the glass as is indicated by the sketch before us. Cannot you make a flat stage from the front of the house over the Vine border and flue, and as wide as is convenient? If, as we presume is the case, the front of the house is glazed, good plants would flower there in winter if the temperature did not fall below 50°, but not if they are densely shaded by the Vines for a month in the autumn.

Propagating Lombardy Poplars (*E. J. C. B.*).—You must employ well-ripened wood of last year's growth for cuttings, which should be cut into lengths of not less than 9 inches or 1 foot. The last is preferable if the

wood for the cuttings is abundant. The sooner they are inserted the better; any time will do for this operation after the fall of the leaf in autumn, but it should not be left until too late in the season or success may not follow. The cuttings of Poplars are generally inserted on ground sufficiently far apart so that they will have room to grow for two years, when they are of a suitable size for transplanting singly if they have done well. You have been rightly informed about leaving two eyes above ground, the best being selected when they have fairly started into growth and secured to stakes to keep them straight and to save them from being broken by the wind. We cannot inform you where you can obtain seed of Paradise stocks, these stocks being raised from cuttings. Even if you could obtain seed many worthless varieties would probably be the result.

Melons for Frame Culture (Amateur).—Monro's Little Heath Melon is of easy culture, but only second-rate in quality; and you are right in attempting the cultivation of some other superior sorts. The probable cause of your failure with Mann's Hybrid was insufficiency of heat, more especially bottom heat. All Melons, with the exception of Little Heath and the old Cantaloupe, require a bottom heat not lower at any time than 65°, while from 70° to 80° will better suit them. The top heat to be at much the same figures. Your soil also may have something to do with the failure. Good clayey loam taken from immediately under the turf of a pasture, with a little slaked lime added, will grow good Melons. It should be made very firm, and never be allowed to become dry. The Victory of Bath is still one of the best for frame work, being free and good, but not very handsome. Hero of Lockinge is rather small, but first-class in every other respect. If a larger green-flesh variety be preferred, then try Eastnor Castle. Blenheim Orange is the best scarlet-flesh variety, and is well adapted for frame culture.

Statice profusa (Salto).—Although this and *S. Holfordii* are greenhouse plants, yet, if the temperature of the house is very low, they make remarkably slow progress. If the plants are young, and large specimens are desired, place them in a stove or intermediate house, a night temperature of 60° being very suitable for them while growing. If healthy plants are started with—say, early next month—fair-sized examples can be produced in a season by the aid of warmth and moisture. The young plants should not be tall to start with, but dwarf, with their foliage down to the soil. The last-named is a much stronger-growing variety than the former, and will not branch so freely unless measures are taken to compel it to do so. Assuming they are in 5-inch pots, when these are fairly filled with roots transfer them to pots 2 inches larger, and when the roots have taken well to the new soil pinch out the centre of the plants to compel them to break back. Until the plants are placed in pots sufficiently large they should never suffer from insufficient root room. The soil best adapted for them is rich fibry loam, a little leaf mould and decomposed manure, charcoal broken moderately fine, and a liberal quantity of coarse sand may be added to keep the compost porous. While growing, these plants require abundance of water, but care must be exercised in giving it, especially for a time after potting, and until their roots are working freely; and at no time must the soil be saturated, or the foliage will shrivel and fall. During winter, until the plants attain a specimen size, do not keep them in a lower temperature than 45° to 50°, and as soon as the season for growing has again advanced push them forward in the temperature named above. Do not maintain a close confined atmosphere while the plants are growing in heat, or they will soon be unhealthy. Give them air daily when favourable, except for ten or fourteen days after potting, until the roots commence working, when they are better kept close. During bright sunshine in summer light shade is necessary. Particular watch must be kept for thrips and other insects, which, if allowed, quickly arrest the growth of the plants. The plants drop their leaves from various causes, but we cannot indicate the exact cause in your case, as you afford no information to enable us to do so. The soil may be sour; if so, remove carefully a portion of it and repot in clean well-drained pots in the compost recommended, place the plants in heat, and water carefully until root-growth commences.

Plant Groups in a Conservatory and Corridor (W. S., Beckenham).—You are quite right not to have staging, and the borders round the sides show clearly that the best method of arrangement for the conservatory will be to plant the borders with sufficient tall-growing shrubs and plants to eventually fill the space without crowding, the number being determined by the size of the borders; or plant thickly for an immediate effect, taking care to give the best positions to the permanent plants, and subsequently remove the others as may be necessary. If you have other houses affording a supply of flowering plants in due succession throughout the year, then thin planting would afford space for groups of flowering plants in pots, so that the house could be kept bright by frequent relays of fresh plants. The permanent plants should be a mixture of such Palms as *Corypha australis*, *Lantana borbonica*, *Phoenix reclinata*, *P. dactylifera*, *Sabal Blackburniana*, *Chamaerops excelsa*, *Areca sapida*, *A. rubra*, and *Seaforthia elegans*, all answering well in a greenhouse temperature. Then there are *Dracaena australis*, *Cordylina indivisa*, *Yucca aloifolia*, *Y. aloifolia variegata*, *Y. filifera*, *Y. quadricolor*, *Phormium tenax Veitchii*, *Aloe prolifera*, *Araucaria excelsa*, *Musa Ensete*, *Pittosporum Tobira variegatum*, all with ornamental foliage; and as flowering shrubs *Camellias* are unequalled, and of which we name a dozen good varieties—three white: *alba plena*, *Mathotiana alba*, and *fimbriata*; three striped: *Lavinia Maggi*, *Bonomiana*, and *tricolor*; three crimson: *Reticulata flore-pleno*, *Bealii*, and *Madame Lebois*; three rose: *L'Avenir*, *Valtevarado*, and *Sarah Frost*. Indian *Rhododendrons*, too, are worthy of a place; but although they keep healthy under the shade of creepers, yet they do not then flower so freely as *Camellias*. *Javanicum*, *Taylori*, *Prince Leopold*, *Duchess of Edinburgh*, *jasminiflorum*, and *fragrantissimum* are all good, and there are many other varieties if you can find space for any of them. Give those which you plant as light and airy a position as possible. *Selaginella Kraussiana* makes a charming green fringe to conservatory beds and borders, imparting to the outlines an attractive, soft, yet bright aspect. The front outlines of your borders need not be flat or angular, but might pleasingly swell gently into a series of semicircles. In the corridor two methods of treatment present themselves for choice—either formal borders along each side, in which *Roses* are planted to be trained up under the roof, with *Ferns* not upon a uniform flat surface, but upon mounds and in hollows, with two or three *Tree Ferns* springing boldly up on each side. A few blocks of wood covered with moss bound on loosely with wire, enclosing a little soil upon

the wood, with *Begonias*, *Iresines*, *Selaginellas*, *Tradescantia*, and *Panicum variegata* planted in the moss, and a *Lomaria gibba* at the top, tell well among the *Ferns*, imparting colour, brightness, and variety; and overhead pendent from the roof there may be hanging baskets or wire containing *Selaginella caesia*, so lovely with its long bluish-green trailing growth; or the corridor might have a winding path among raised beds of rockwork, with plenty of nooks and pockets for *Ferns*. There will be ample space at the garden entrance for a fine specimen *Tree Fern* on each side the door.

Names of Plants (An Inquirer).—The shrub with yellow flowers is *Chimonanthus fragrans*, the other is *Swainsonia galegifolia*. (C. W.).—1, *Nephrolepis davallioides furcans*; 2, Some particulars respecting the habit or flowers are necessary to aid us in naming this; 3, *Alocasia metallica*.

THE WELSH BREED OF CATTLE.

It is notorious that amid the enthusiasm of breeders in reference to other breeds, the Black Cattle of Wales have been almost as much disregarded as though they did not exist, and it is therefore our intention to give the best information respecting the style and characteristics of the several variations of the breed to be found in the different districts in Wales. The Black Cattle are natives of the counties of Pembroke, Carmarthen, and Cardigan, and are subdivided into Castle-martin and Dewsland breeds. From Cardiganshire they also extend along the North Wales coast up to Anglesea. We learn from an article in the "Live Stock Journal Almanack" of the present year that Mr. Richard Harvey, in his preface to the "Welsh Cattle Herd Book," says, "The cattle are generally of a black colour, and frequently with white marks on the udders of the cows, also a few white hairs at the end of the tail. Sometimes a few white hairs are mixed up with the coat, but this is not always hereditary, and only comes out occasionally. A brown-black, approaching chocolate, is considered a good colour. Occasionally there are some cows striped red and black, also some quite white, with black ears, muzzles, and feet, but these are becoming very rare. The late Lord Dynevor had some very fine specimens of the white breed near Llandilo, and the five-year-old oxen were very fine animals. The horns should be of a rich yellow. They are generally tipped with black, and do not come out yellow to the very end like the Herefords. There is a different pitch of horn for bulls and cows. A bull's horn should be low and well spread, the cow's narrower and the pitch more upright. The steers and oxen take more after the bull. This description applies in a great measure to the Anglesea cattle. They are, however, broader on the back and shorter in the legs with more hair; the heads are heavier and horns not so yellow.

Mr. Morgan Evans, who is one of the best authorities as a breeder of Welsh cattle, took exception to portions of the above description by Mr. Harvey. He says he never saw a black cow with a brown face. He has seen cows in Pembrokeshire with a

white line along the back, and with white along the belly as well; but he prefers a rich brown-black, which is a favourite colour with some breeders, and he has great partiality for cattle of this hue. They are generally more kindly feeders than those which have coal-black coats. The brown-black, however, should not be approaching chocolate, for there should be no reddish tinge—a sure sign of cross-breeding—and such animals usually lack quality. The coat should be long and wavy, neither short and crisp nor very curly. A brown-black wavy coat is to be preferred to any other. A white udder and a grey or white tuft of hair at the end of the tail is the only deviation from the self-colour, black, or brown-black, admissible. The natural characteristics of the breed may be described as narrow on the shoulder and chine, slack on the loins, an inclination to be high on the rump, and flat-sided. The special characteristics of the blacks which make them so valuable, are hardness of constitution, aptitude for dairy purposes, and docility.

The shape of these animals over the shoulder top and chine is, we have always considered in our experience, the true characteristic of a good milking capacity, no matter in what breed of cattle, for as a rule where cows are heavy in the fore-quarters, with heavy pads of flesh on the shoulder top, they cannot be made good milkers by any known system of feeding or management. We must therefore conclude that as these Welsh Blacks are described they may by special care in selection and management be made to produce cattle in one case excellent milkers, and in the other where perfect shape and tendency to fatten is required, good graziers and of early maturity. Further on we shall produce evidence to justify these conclusions by some of the best judges of the breed and the most intelligent managers not only for home use but also for the production of prize-winning animals.

Let us now refer to them as dairy stock ever under the most adverse surroundings, such as the food afforded by the mountainous districts of Wales. In the first place they must be extremely hardy and possessing the strongest constitutions such as we find in no other race of cattle kept, and enduring hardships in the same way. There can be no doubt on the point if we consider the practical treatment of rearing calves, and the hardships they endure before they are old enough to breed and contribute to the milk pail; the greatest astonishment is connected with the fact that they are ever capable of becoming useful dairy stock at all, after having been reared under such hardships as they have to contend with. No cattle can withstand cold and wet so successfully as the Welsh Blacks. Their native home is in a stormy clime, and they roam in the fields, their only shelter being the earth banks of the enclosures and the mountain sides. Cows and heifers are frequently allowed to calve in the tempestuous atmosphere of the western districts knee deep in snow, with apparent comfort and without injury to their offspring. But to ascertain the value of animals with such constitutions and capabilities, let us compare them with those animals which are said to rough it in the New Forest and other commons or districts such as the commons of Surrey, Hants, and other Heather districts, for these districts can claim only a nondescript kind of cattle, although the feed on such lands are of the poorest. Yet the climate of the home and southern counties is greatly superior to the coast districts of Wales, and it seems most extraordinary that owners of such cattle should continue to rear and use them for dairy purposes. For although fairly productive of milk, yet when barren from accident or otherwise they are completely worthless; while in Wales the black cattle after undergoing such hardships as we have described both in food and climate, any barren animals after leading a beneficial life for the owner as dairy stock are actually capable and frequently are fed and converted into excellent carcasses of beef, and sometimes they are exhibited in the district cattle shows with success after a judicious course of feeding and management.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Should the late mild and comparatively favourable weather last the seed time for spring Wheat may be continued with a fair prospect of success, for the land in most cases, although rather heavy on strong clay soils, is yet workable and suitable for Wheat-sowing. Upon the other hand, Beans and Peas may now be sown with a fair prospect, especially where the nature of the soil is undulating on the surface and friable in working. At the same time we should take or select the driest soils for Peas and the heaviest land for Beans. The latter, however, are uncertain croppers, and we prefer to drill with the Beans either small Maple Peas or winter Vetches, in which case if the black aphides should attack the Beans there is a probability of the Peas or Vetches succeeding and insuring a crop. In the event of the mixed corn being drilled at 20 inches or 2 feet distance between the

rows the land can be kept clean by horse-hoeing between the lines, and hand-hoeing and weeding in the lines until the Peas or Vetches begin to spread, after which they will meet each other across the drills and effectually overwhelm the weeds, but especially the annuals. Barley and Oats may now be sown with a fair prospect of a good crop if the land is in good heart and condition; if not, artificial manures should be drilled with the seed. Most manure merchants keep for sale mixtures adapted for the purpose, but we prefer to mix for ourselves such manures as we have found the best for this purpose, for Barley using 2 cwt. of bone superphosphate and 1 cwt. of Peruvian guano per acre. For Oats or drege, however, there is nothing equal in our opinion to sowing broadcast from 1½ cwt. to 2 cwt. of nitrate of soda per acre, according to the previous condition of the land, especially as it is now so much cheaper than previously. The pastures may some of them soon be dry enough to bear the horses and carts without tracking injuriously, in which case the sooner the dung or composts are laid out the better; if not, artificial manures may be applied with great advantage, especially in February, when we generally obtain a sufficient rainfall to increase the benefit to be derived from artificial manure dressings. It has been stated by some agricultural chemists that dressings of artificial manures cannot be depended upon to fully operate upon pasture land; but our experience is quite the reverse, for we find that 3 or 4 cwt. of bone superphosphate and 1 or 2 cwt. of Peruvian guano in admixture is excellent, yet on some dry soils 1 or 2 cwt. of nitrate of soda instead of guano has been found to answer better.

Hand Labour.—We have men now engaged in planting an orchard—namely, Filberts and the two best varieties of Cobnuts, also fruit trees, of which we are planting nine sorts of kitchen and table Apple trees—viz., Lord Suffield, Blenheim Orange, Wellington or Dumelow's Seedling, Worcester Pearmain, Keswick Codlin, Orange Pippin, Hawthornden, King of the Pippins, and Cellini Pippin. These are being planted on some fine hazle loam, with mild brick-earth subsoil, on south-west aspect, well sheltered from north and east. Some men are employed in the spreading of chalk, grubbing hedges, &c., ditches to be drained. Threshing of corn before the busiest period for labour commences will employ some men, especially in winnowing after the threshing machine. Some machines will winnow corn, &c., simultaneously, but it is rarely the case that the winnowing is so perfect as for every sackful to be alike in sample, at least we have found it to be the case frequently; and this oftentimes induces the miller to grumble, and some will take advantage and refuse to accept it as representing the sample, especially on a falling in the market. This is a very troublesome matter to contend with, and therefore we prefer to thoroughly mix the grain and minnow it carefully to insure a uniform and saleable sample. Although it is extra labour, yet it prevents further trouble in marketing.

Live Stock.—The Down flocks of every variety, either South Downs, Shropshire Downs, Oxford Downs, Hampshire Downs, and their crosses, all are now near to or are in the act of lambing, but more especially the Hampshire and west country Downs, including those bred in Wilts and Dorset. Nothing could be more favourable than the weather has been for all of these during gestation and those which have now brought their lambs, for the whole autumn has been more mild, moist, and forcing for grass than is frequently found to occur in the spring months. This has therefore tended greatly to favour good health and condition amongst not only breeding ewes but all breeds of fatting sheep feeding upon roots on anything like dry friable land, for these have done remarkably well, and it is probable that more mutton was never made upon a given number of sheep fed in the open field upon roots and the accompaniments of good hay, corn, or cake than during the past autumn and up to the present time. This is well for the consumer, as mutton must be more moderate in price in consequence; but it has been and will be much against the grazing farmer who paid high rates for his sheep on the first purchase, and we fear that notwithstanding the short number of sheep stock in the kingdom the farmer will gain but little this winter by fattening his sheep.

REMARKS.

13th.—Sharp frost on grass early; fair throughout, but not bright.

14th.—Fair and dry.

15th.—Fine throughout.

16th.—Dull and misty, with fog at times.

17th.—Overcast, with slight fog.

18th.—Dull and gloomy.

19th.—Dull, calm and cloudy, clearer in evening.

Another warm week, with extremely high barometer, no rain, dull & variable weather, scarcely any wind, and slight fog.—G. J. SYMONS.

ARALIAS.

UNTIL within the last fifteen or twenty years the Aralias cultivated in gardens in this country were limited to several shrubby ornamental species of North America, of which *A. spinosa* and *A. racemosa* were perhaps the most popular; one or two from Japan, and about the same number from the Old World tropics. Since that time, however, improved means of intercourse with British possessions in Polynesia have offered facilities for the introduction of many of the beautiful plants with which these regions apparently abound, and, along with scores of richly coloured *Dracenas*, *Crotons*, and other plants, a number of distinct and handsome Aralias have found their way into English gardens. Graceful in habit, free in growth, and easily multiplied, these tropical Aralias have found general favour; and the many uses for which their distinct beauty and robustness of constitution make them specially fitted have been readily appreciated in all gardens where their requirements as tropical plants can be supplied. No doubt an improved and more comprehensive taste in horticulture has led to the more frequent employment of the hardy species in the formation of shrubberies, and also to a more general use of the greenhouse sorts for purposes of decoration, so that we have now between twenty and thirty distinct and handsome Aralias, comprising both hardy, greenhouse, and stove decorative plants.

Of the first of these, the hardy species, the most generally known is perhaps *A. spinosa*, a native of Virginia, the introduction of which dates back some two hundred years. It is called by the North Americans the Angelica Tree, from the resemblance of its foliage to the Angelica. As a low, and, on good soil, compact-growing shrub, it is one of the best and most distinct plants for the outdoor garden, its large twice or thrice-pinnate dark green leaves, which are borne on stout spine-covered stems, contrasting with fine effect with other leafage. A moist loamy soil in an open position causes it to produce leaves from 2 to 3 feet in length and almost the same in width, and in the summer to bear large bunches of white Ivy-like flowers. It may be propagated either by means of portions of the stem or by cutting the stoutest of its roots into lengths of 3 inches.

A. hispida, another North American species, and *A. racemosa*, from the same country, are somewhat similar to the above, though not so tall-growing. The former has a spiny stem and bipinnate leaves, and bears in July large long-stalked umbels of white flowers. *A. racemosa* is almost herbaceous-stemmed, has leaves of about half a dozen ovate segments, and does not bear spines upon its stem.

A. japonica, generally known as *A. Sieboldii*, is almost if not quite as useful a plant as *Ficus elastica*. In pots it is of great service for furnishing purposes; for window gardening it has very few equals, and for summer bedding out of doors it is now largely employed as a specimen or for grouping with dwarf flowering plants, as ground upon which its bright green hand-shaped leaves are effectively displayed. In

Regent's Park last year some very striking beds were arranged with this *Aralia* as the principal object. Thousands of plants of this species pass through Covent Garden Market almost weekly; it is, in fact, now one of the most popular of market growers' plants. In the south of England plants of this *Aralia* have stood out of doors for several years; in fact, it may be said that, with a sheltered position, such, for instance, as is necessary for some of the *Magnolias*, *A. japonica* is a hardy plant. For its propagation seeds—which are now to be had from most seedsmen—small pieces of root, or the stem cut into lengths similar to what is done in the case of Vines, are all equally reliable methods. A temperature of 65° to 70° will cause the stem or root-cuttings to strike in about a month. By growing the young plants in a moist intermediate house they soon form useful specimens, which may be hardened off and employed in many ways without suffering much either from gaslight or exposure.

A. reticulata is a yellow-veined variety of great beauty, the rich reticulation of bright yellow upon a ground of bright shining green giving the foliage of this plant an unusually ornamental character. *A. variegata* is another handsomely marked form of *A. japonica*, the foliage of which is margined and patched with yellowish white. These variegated forms are not quite as hardy as the type, but in a cool greenhouse they are quite at home. *A. dactylifera* is a long-lobed form of garden origin. This may or may not prove to be a variety of *A. japonica*; it has the appearance of a variety at present.

A. papyrifera, the Rice-paper tree of the Chinese, is a tall-growing, large, woolly-leaved species, suitable for planting out in a cool conservatory or for a sheltered position out of doors in the warmer parts of this country. The whitish wool which covers the leafstalk and almost hides the green of the palmate blade is not an unattractive characteristic of this plant. In winter, and sometimes again in summer, the large panicles of sweet-scented flowers are borne in great profusion, and last upon the plant for several weeks. It may be propagated in the same way as advised for Siebold's *Aralia*.

A. crassifolia and its variety *punctata* are both tall straight-stemmed greenhouse plants, with long narrow leaves, along the margins of which is a row of spine-tipped teeth, which give the foliage a fish-bone appearance. The orange midrib, dark olive-green surface, and stiff straight arrangement of the foliage, are singularly striking in these plants. They are both natives of New Zealand. I have not tried propagating them by means of roots, though it is likely that it might succeed. The top may be taken off and rooted, and the laterals, which will be pushed after its removal, form suitable pieces for cutting. The stem, if laid on cocoa-nut fibre heated to 80° and kept moist, will push up a number of lateral shoots, which may be removed and placed in the propagating frame to strike, or be left upon the parent stem until they have formed roots. *A. pentaphylla* and *A. trifoliata* have digitate 3 to 5-foliate leaves, are both tall-growing greenhouse plants, but have not any particular characters to recommend them for garden purposes.

The stove species of *Aralia* take rank among the first of ornamental-foliage plants. The most graceful of all are *A. Veitchii*, with its variety *gracillima*. Nothing can surpass the elegance of habit and the delicacy of foliage of these two plants, the variety being especially beautiful when young. For the decoration of the dinner table we have no better plant than this, and perhaps there is no plant in greater demand for such a purpose. The fine line-like, dark olive green, undulated leaflets, which are arranged in sixes or eights on the apex of the thin petiole, and the erect habit of the plant, are precisely those characters which are most effective in table decoration.

A. elegantissima is almost as beautiful, lacking a little of the grace of *A. Veitchii*, but distinct in its broader-toothed

leaflets and almost black stems. *A. leptophylla* belongs to the same group, differing from those previously mentioned in its possession of a short stalk to each leaflet and the absence of the teeth along the margins. Although the plants above named are distinct from each other when young it is not unlikely that they are forms of one variable species, the *Aralias* being known to be somewhat heteromorphous in a juvenile stage. So far as is known none of these plants have borne flowers in this country.

A. Guilfoylei is a variegated-leaved species, of handsome appearance when young. The foliage is pinnate, the leaflets being serrate and margined with white, the inner portion being here and there splashed with grey. *A. reticulata* has long linear entire foliage, and is rather graceful in habit, but is used principally as a stock upon which some of the kinds are grafted. *A. Chabrieri* is a recent acquisition, and is a handsome fine-foliage plant. The leaves are arranged in a distichous manner along the branches, and are narrow-linear in shape, their colour being olive green with the midrib and nerves of dull reddish tint. In addition to these there are *A. Osyana*, a dark-coloured digitate-leaved species, with ovate-lanceolate leaflets; *A. splendidissima*, a large-growing species with gigantic foliage like Ash leaves; and several others, none of them being worthy of particular mention. Those plants which are called *Aralias*, but which belong to the genus *Panax*, such as *A. filicifolia*, &c., are purposely omitted here. *A. souchifolia*, a curious-looking plant with irregularly shaped and blotched foliage, belongs really to the genus *Meryta*. The plant known as *Terminalia elegans* is most likely a species of *Aralia*, and may be increased by grafting it upon *Aralia Guilfoylei*, although it strikes fairly well in the spring.

For the propagation of the stove *Aralias* grafting must be resorted to, at least for some of them. Those which may be raised from cuttings are *A. Guilfoylei*, *A. reticulata*, and *A. Chabrieri*. The young stems of these may be cut into pieces with about three buds to each, and if possible foliage also. Plant them in pots of silver sand with a little peat below it, in which the roots will be able to find nourishment when they have formed. A close frame or bellglass should be placed over the cuttings, and a temperature of 75° maintained, with shade from sunlight and a saturated atmosphere kept about them. When strong enough, the two first mentioned species may be used as stocks, upon which those requiring to be grafted should be worked. Cut off the top of the stock to within 2 inches of the soil, and select stocks and scions of about equal thickness. A single bud with a portion of the internode below it is sufficient to form a scion. Splice grafting is the most convenient for these plants, and if neatly performed the union will be almost imperceptible when the plants have grown a little. Place the newly worked grafts in a handlight or frame similar to that advised for cuttings, and subject them to the same treatment. In about a month the union will be perfected, and the plants may then be placed in pots of convenient size, using a mixture of loam and peat in equal parts, with a sprinkling of silver sand. When the plants are ready to shift into larger pots a little dried cow manure may be mixed with the soil. A well-drained compost, so that plenty of water may be supplied to the plants without any danger of sourness or soddenness resulting. A tropical stove temperature with a saturated atmosphere and shade from bright sunshine are the conditions necessary to the successful cultivation of stove *Aralias*.

As the plants increase in height their foliage becomes larger and less graceful, so that it is always a good plan to cut them down and graft them again. If the stocks are too thin to take the stem of old plants, then, instead of cutting the stem down, remove the top and graft it upon one of the strongest stocks; the latent buds on the stem will then push into growth, which when long enough may be worked on to stocks. Unless a large number of plants are required this latter plan is by far the best, as the side shoots take quickly and commence to grow at once. *A. reticulata* is the most

suitable stock for *A. Veitchii* and its variety *gracillima*.—W. W.

FORCING VEGETABLES.

To have an abundant supply of really good forced vegetables during the winter months—say from the middle of November onwards—is by no means a difficult task where there are ordinary means at command, so that the amateur or cottager may have a fair supply without taxing his skill to any great extent or by giving much labour. Having occasionally been put to the test, when renovating old places or forming new ones, of producing abundance, our inventive powers have been called into action to supply articles from the garden much in request during winter. Last season, probably more than at any other period in my recollection, I had to apply rough and ready means to meet the demand.

Mushrooms, perhaps the finest we have seen, were from boxes filled with ordinary stable manure trodden firm and treated in the usual way, the lids being kept close till the Mushrooms appeared. They supplied abundant crops of remarkably large Mushrooms, much finer than on ridges formed in the old-fashioned system largely practised by market men, which we also had recourse to; but while a place is swarming with tradesmen even these ridges are in the way. Where there are sheds or other erections where Mushrooms can be cultivated it is generally preferable to grow them in such places, as ridges give much trouble uncovering to gather the crop during inclement weather, and it is only in few places where space can be afforded to have littery ridges standing about. In stables, cowhouses, and similar structures we have had all we could desire in the way of Mushrooms with a minimum of trouble or expense.

Seakale-forcing, though simple, is done less successfully by amateurs than might be expected. Some proprietors will insist on having it forced in the old-fashioned way with pots and fermenting material, because they maintain that blanching is more complete, and the appearance is better when served, and, we may add, often more tender than what is forced in Mushroom houses and other heated structures. Last season we placed a few boxes with close-fitting lids in a heap of fresh-collected leaves, placed the roots of Seakale closely and upright in the bottom, with room for the crowns to sprout about 8 inches or so. The whole was covered with more leaves and some branches of trees placed over them to prevent their being blown about by wind. The produce was excellent. Other means were adopted to meet our requirements, such as a square pit dug out and lined with boards and covered with leaves and litter, and later in the season the crowns were packed close and covered with old partially decayed manure, which answered well; while in the open ground soil is drawn over the crowns, where they grow and blanch easily. In strong clay or marly soil this method does not suit well. A covering of clean leaf mould, old tan, such as is usually adopted when Hyacinths are newly potted, is preferable to using the ordinary soil.

Rhubarb was lifted intact, packed closely together, covered with strong crates, leaves and litter built round them, and some litter thrown over the top, which was easily removed to gather the Rhubarb, which was in great abundance from the beginning of December till it was gathered in the open ground. Some roots placed in boxes in a shed where the mechanics assembled to have their meals did fairly well, but not equal to the roots placed in crates. A baker in our district told me he sold over £10 worth of Victoria Rhubarb last year raised in a corner behind his oven! In such positions much care is necessary to prevent the stalks becoming dry and tough. Plenty of moisture judiciously applied obviates the evil.

Asparagus was had in quantity by placing a square box about 3 foot deep over a heap of collected leaves mixed with a little litter, on which the roots were packed in the ordinary manner and covered with light soil. A mat did duty instead of glass, and while weather was severe extra covering was added.

Peas for planting out in March were raised in an outhouse sown in boxes thickly, and when the Peas were through the soil they were placed in front of an old building with pieces of wood in short lengths placed along, resting on the wall, to keep the coverings off the Peas, which were exposed during the day when mild but covered at night. About the middle of March these Peas were planted out and closely staked, and we never remember seeing Peas grow so freely. They began to yield pods about the 20th of June. The season was late, and said to be the coldest spring and summer ever remembered in this district. Now that new structures have taken the place of "makeshifts," bottom and top heat of the most modern and efficient construction, an abundance is supplied with a minimum of trouble;

and while we decidedly prefer means to meet our requirements, we do not despise the "days of small things" of last season—M. T., *Stirlingshire*.

TRANSPLANTING LARGE SHRUBS—MAKING A HA-HA.

How should a shrubbery be planted? With large costly specimens put far enough apart for full development, or with smaller plants set thickly to clothe the bare earth for a certain immediate effect? Both for economy and expediency I prefer the latter method, the only attendant or rather resultant disadvantage being the necessary repeated thinning of fast-growing shrubs, till at length it becomes difficult to find space for all of them. If this very natural result of free healthy shrub growth were taken into account at first, and economy kept well in view, the whole of the shrubbery would not be made at once, but gradually, so as to afford space for every growing shrub; and what is of even more account, keep some fresh feature to be added to the garden yearly. Without expecting everyone to agree to this protracted method of laying out a garden, I am sure that many will appreciate the pleasure and advantage to be derived from it. Of this I am able to speak positively, as I have for several years been engaged in this interesting work of the gradual development both of dressed grounds and wild-like woodlands. It is to some of the work done this winter that I now wish to call attention.

Some large masses of Rhododendrons had become so much crowded that thinning and re-arrangement was desirable; but the work was not to be undertaken lightly, for most of the shrubs were from 6 to 8 feet high, many of them as much in diameter, and there were several hundreds of them. After the re-arrangement the surplus

Fig. 12.

stock was certain to be large; what was to be done with it? It was resolved to add two acres to a conspicuous lawn where the outlook was somewhat tame, and to make there six large raised beds for the surplus shrubs, with soil obtained close at hand by making a ha-ha or sunken fence along the new enclosure. The obvious advantages of this plan were a picturesque effect, economy of labour, and a comparatively inexpensive enclosure, the only part of the ha-ha that could be regarded as a separate expense being the building of a turf wall against the back of it. The turves were a foot square, 2 inches thick, and they were laid flat upon each other. The cost of such a wall is trifling in comparison to one of brick or stone. The turves soon grow together, the front becomes clothed with verdure, and its soft green hue is infinitely preferable to the harsh uncompromising effect of masonry. Careful building is, however, important, for, however skilful the turf-cutters are, some of the turves are certain to prove uneven, and if they are not laid truly and well the wall may fall. To avoid risk I have had stays and pieces of rough board put at intervals along the wall (A, fig. 12), and 2-inch pipes, as at B, put at intervals through the turf near the bottom to prevent any accumulation of water behind the turf. The stays will remain till the turf has grown together and is quite safe.

The soil was excavated and wheeled to the raised beds a distance of 30 to 40 yards for 1s. 0½d. per cubic yard. This price may appear high, but in reality it was not so, for there was a foot or more of gravel at the bottom, for which picks had to be used, and the dressing of the slope was included in it. The men—many of them skilled navvies—earned 2s. 10d. a day; in summer they would probably have earned 3s. 6d. If the subsoil had been easily worked the cost would have been from 2d. to 4d. less per cubic yard. I mention this to show how impossible it is to arrange a common rate of pay for such work. The only fair way is to have one or more sections opened, and then to prepare an estimate of costs beforehand.

If set about in the right way the lifting of large shrubs is an easy and expeditious operation, without risk or damage; but in careless ignorant hands there is not only much loss of time, but a very considerable risk of a subsequent loss of many valuable shrubs. I happen to live near a large nursery, where most of the labourers of the neighbourhood have been employed, yet anything like intelligence in doing similar work to what they must have done there is certainly the exception rather than the rule. The crowded masses

of Rhododendrons were each begun at one end, a trench opened half way round each plant, the soil worked well away from beneath the ball of soil and roots, and then a spade passed down through the soil round the back of the ball, care being taken not to cut into the ball, but to keep the spade upright. A long 2-inch plank was then thrust under the wall as a lever, a short plank being laid on the edge of the hole for a fulcrum, and with one heave a couple of men could lift the plant level with surface, and then moving round with the end of the plank the shrub was dropped upon a sleigh consisting of a piece of broad plank with a couple of runners beneath and ropes fastened to one end, and at once pulled aside out of the way. Without the lever and sleigh how difficult and tedious the work is. To lift a large shrub in any other way with 5 or 6 cubic feet of soil and roots is not easy, and too frequently the ball is reduced so much that the shrub suffers severely. For removal to a distance a low hand-truck was used. In this truck the principle of leverage is again used, the handle being at an obtuse angle to the body of the truck, so that by tilting up the handle and thrusting the truck under the ball of a shrub tilted over for this purpose, the handle has only then to be depressed and the shrub is lifted and wheeled away.

In replanting due care was taken to insure the free growth of root and branch next season. The old beds had a surface dressing of several inches of fresh soil, and they were trenched, but all the good soil was kept on the surface. In this a portion of the shrubs were carefully settled, and the recent unpleasant damp foggy weather has certainly been good for them.—EDWARD LUCKHURST.

EAST LOTHIAN STOCKS.

Stocks must be familiar flowers to all readers, as every seedsman's catalogue contains their names in great variety, and the German, Brompton, Cape, and the Emperor strains have been long and widely known, but the East Lothian Stocks are seldom classed with these in books or gardens, as they are generally treated as specialties, and they deserve this distinction, for of all Stocks they are undoubtedly the finest. It may not be known to all that these were originally brought into notice by Mr. David Thomson, who wrote interestingly of them in these pages, and astonished everybody with the gorgeous displays in the flower garden at Archerfield. In this way a guarantee of their excellent characters was given, which they have retained ever since; and as several nurserymen, especially north of the Tweed, make it their business to preserve the strain in its original purity, we may confidently expect to find their valuable characteristics maintained for a long time to come. There is scarcely room for improvement, as their habit of growth and colour of bloom are all that could be desired. They grow very dwarf so far as the leafy wood is concerned, but they produce wonderful spikes of flowers. The colours are distinct and striking, and as a trio are unequalled. The white pure, the purple deep, and the scarlet intense.

Their decorative qualities are not confined to one particular, but they may be used in many ways with effect. In the flower garden proper they form charming beds or rows, and in mixed borders they may be pleasingly grouped. Being so much inclined to bloom and little disposed to make superfluous leaves and wood, their whole habits render them most suitable for growing in pots for greenhouse and conservatory decoration, and for this object alone they merit attention, as they are exceedingly showy and fragrant in the conservatory.

In cultural requirements they do not differ from the most common or poorest of Stocks. They are easily reared, hardy in their matured growth, and reliable in all localities. From the middle of January until the end of March is the time to sow seed to produce plants for blooming in summer and autumn. From the earliest sowing they will commence flowering in June and July, and continue until December. Seed sown in April or May will give plants which will be ready to shift into 6-inch pots in July, and if grown in these the plants will bloom profusely in November and onwards. Now and in spring the seed should be sown in pots or boxes in a little heat, and the plants may be transferred to other pots or boxes, or the whole may be dibbled into a frame, and in any case they should be grown so as to be quite hardened by the beginning of May, when they may be planted out. Plants for autumn and winter blooming do not require to be reared under glass, but will do quite well out of doors.—J. MUIR.

PEAR JOSEPHINE DE MALINES.

THIS is the best Pear of its season—clear-skinned, smooth as ivory, pleasant to the eye—no doubt what Josephine herself was fifty years since, when Major Esperen, with the true instinct of a military eye and the heart of a husband, dedicated this, his best bantling, to his partner. Delicious to the taste, luscious and piquant, Madame could have received no greater compliment from the Major than this dedication. The Pear is not coarse but agreeably modulated in size, with a tender tinted flesh from the rind to the core.

Sometimes in our ungenial climate it is tardy in ripening, and this year my Pears were apparently hopeless. Fortunately, a houseful of Maréchal Niel Roses just bursting in bloom suggested that the fruit should have the benefit of the heat. In three days the unripe Pears changed into the sweet and tender Josephine de Malines. No man can desire better.—T. F. RIVERS.

[Specimens accompanying this letter were very delicious.]

DENDROBIUM MONILIFORME.

I SEND for your notice a spike of this beautiful early-flowering Orchid. It is a plant that all cultivators of fine-flowering stove plants should possess. Our largest plant of it has just had 450 flowers upon it, and without any forcing the first blooms opened on Christmas day. It is a plant of the easiest culture, requiring the ordinary stove treatment. The only point that I have noticed which should be avoided is much exposure to the sun in summer; still no shading is necessary when the plants are a little distance from the glass. Place them on the surface of well-crooked pans, turfy peat and sphagnum being packed round the roots. Young growth is necessary to lay the basis for free flowering, and this is insured by providing plenty of moisture in the atmosphere in the summer or growing season. This Dendrobe flowers uniformly on the previous year's wood, this year's growth retaining its foliage, which gives the plant a good appearance. In autumn after the growth is made we keep the plant quite dry, and in this condition the pseudo-bulbs soon become covered with flower buds, and after these have fairly shown the plant is placed in a slight heat. This Orchid can be relied upon as a first-rate Christmas plant.—ROBT. MACKELLAR.

[Our correspondent sends us with these notes a portion of a healthy pseudo-bulb of *Dendrobium moniliforme* 9 inches long, and bearing twenty-two richly coloured blooms in pairs or triplets, and forming quite a wreath of flowers.]

CULTURE OF HORSE-RADISH.

As Horse-radish is required in almost every household and at all seasons of the year, it is well that the best way of growing it should be more generally understood by gardeners in private places than it is at present. As a rule the Horse-radish occupies the same ground year after year. When a little is wanted it has to be searched for all over the bed, and when found is often not fit for use. Until a very few years ago I was much puzzled to keep up a supply, still I had a large bed devoted to it; at the same time I could see grand samples exposed for sale in the shops—long, thick, white roots, in every way superior to that grown in gardens. I made inquiries among some of the best gardeners of my acquaintance, and also consulted all the garden literature at hand. Some advised cutting a number of old crowns from the bed, planting them about a foot deep in rows; others recommended planting long thin roots in rows. Both plans were followed and answered fairly well, still there were drawbacks. First, by these methods Horse-radish takes two or more years to grow to a proper size, and is always woody and inclined to be black in the centre, while it did not come up to the standard of that in the shops. But eventually coming to live near Manchester, and in the very district where a large quantity is grown annually for market, I was not long in arriving at the right practice, and I cannot do better than detail the advice given to me by a very good grower.

About the end of January commence at one end of the old bed, and carefully take out every piece of root, large and small. Take care of the long, white, thin roots, not less than a foot long and the growth of the previous year. Tie them in bundles and bury them in damp sand. Select all which you think will be fit for use, and bury them in soil or sand. These will do for use while the young ones are growing. Clear the refuse off to be burnt, and prepare a bed or beds in an open sunny position. Thoroughly trench and dress it with decayed manure, which must be well mixed with the soil. At the end of February or the beginning of March take the young roots or sets out of the sand, and it will then be easy to distinguish the crown end, as there will be a number of buds or small sprouts round it. Obtain a piece of rough cloth and rub the entire length of the set with the exception of about an inch at each end, the object being to remove all buds which would afterwards become roots and disfigure the size of the main root. In planting mark out the beds 3 feet wide, leaving as much soil in the alleys as possible. Lay the sets 15 inches apart in a horizontal position across the bed, the crowns to the walk down both sides of the bed, then cover them 2 inches deep with soil from the alleys. When the leaves are about 4 or 5 inches long examine them and take off any roots which may have formed at the base of the leaves. As growth advances mulch well with good manure, and give periodical waterings with liquid manure. Care must be taken during dry weather that they do not

suffer for want of water, or the crop will be very much injured. By the end of October the crop will be ready for use. A sufficient number of young roots must be saved for the next year's sets and treated as before.

It is always well to change the ground every year, for if grown in the same position for two years it is apt to become dark in colour and woody in texture. What is wanted for next summer's supply should be taken up and stored in damp sand or soil. I only know one variety, but a large grower for market tells me there are two, one very much better than the other.—WM. PLANT.

"SINGLE-HANDED."

MAY I ask all who have so promptly responded to my appeal on behalf of a suffering fellow labourer to accept my grateful thanks for the aid they have rendered and the manner in which it has been conveyed? The letters I have received form a treasury of sympathy that must ever be valued by our friend, if he lives, and his family. As typical of these letters I cite from the first that came to hand, and it is the more necessary to do so since the writer withheld his name and address.

"I felt very grieved to see your sad account of the health of your well-known correspondent 'Single-handed,' as I presume in common with most of your subscribers, I experience almost a feeling of personal regard for those whose genial and experienced writings give us weekly so much pleasure and profitable information. I admire the old motto, '*Bis dat qui cito dat*;' and though I cannot send Grapes I can send wherewith to procure some, and I beg to enclose £2, trusting that I may have the pleasure of hearing that it has been of use, and that before long we may once more have the gratification of seeing his *nom de plume* at the bottom of an article. With best wishes.—AN OLD SUBSCRIBER."

That letter is from certainly a good man, and presumably affluent; the other, and the last opened up to the time of writing, is from a gardener, and is equally prized.

"Let me thank you now for your friendly aid to one who is, I am sure, a brother to be beloved. I mean 'Single-handed.' I send 2s. 6d. for him. You can either send me a packet of seed of *Auricula* or not. If there are others more pressing let them have the seed, but let 'Single-handed' have the money all the same. I wish I could make it eight times as much. I do rejoice to know that he is, even as I am, earnest in the temperance cause. May the Great Physician heal him wholly. My warmest blessing he has, now and always.—H., *Notts.*"

Many others have written similarly. There are still a few packets of *Auricula* seed at disposal, which I shall be glad to distribute. It is only fair to state that "Single-handed" has not during any part of his serious illness been in receipt of wages, his sense of what was right impelling him to ask to be suspended from his engagement when he felt his incapacity to do his duty. The cause of his present illness is attributed to three night journeys of 400 miles each and the exertion attending the removal of his family, &c. The sums sent, with any that may follow, are urgently needed, and will be applied to meet the actual necessities of one of the saddest of cases and the best of men in the gardening world.

The supply of Grapes is at present ample, and those who have so generously offered them will be written to as a bunch may be required, and they are now cordially thanked for their kindness.

With the object of affording the best information in answer to numerous inquiries relative to the condition of "Single-handed," I have received the following letter from the skilful medical gentleman who has attended him so assiduously.

"124, Western Road, Brighton.

"January 29th, 1884.

"DEAR SIR,—In accordance with your wish I have pleasure in writing to you with regard to your afflicted correspondent. I saw him yesterday, and found him decidedly worse. He is suffering from, I fear, a malignant form of ulceration of the stomach, and I see no hopes now of his recovery. He looks blanched and bloodless, and is being slowly, poor fellow, starved to death, for scarcely anything keeps down, and I do not think the end can be very far off. He bears his trouble with calm heroic resignation, and it is a source of keen regret to me that I can do nothing further to help him.—Very truly yours, ALLEN DUKE."

It is painful to publish this letter, but in no other form can such authentic information be conveyed; and I have only to add that "Single-handed's" copy of this issue of the Journal will be sent to his medical attendant.—J. WRIGHT.

VINES BLEEDING.

I PROPOSE putting Messrs. Muir and Taylor, who, I see from the note of "Comber," do not believe that Vines are injured by bleeding, to this test: I ask them if they will allow me or my deputy to freshly pare the wounds of all the pruned shoots, &c., three days before starting the Vines in any one of their most important and best vineries about to be started soon. If the bleeding does no harm the paring of the wounds will do no injury, and if their faith is equal to their professions they should not hesitate to submit their Vines to the ordeal. If they decline the challenge I and others of your readers will no doubt form our own opinions about their preaching and practice. I can only account for any

gardener claiming bleeding to be harmless on the supposition that he never saw a real case of severe bleeding. Mr. Muir's Vine that bled "gallons" must have been a very marvellous plant indeed. I never saw a Vine bleed to that extent, and never knew anybody either who did. The most was at the rate of a teacupful (or less) in about twelve hours, and continuing about two weeks, and the effect upon the Vines, and especially upon the shoots which bled, was very debilitating for two or three years afterwards, thus showing that bleeding produces both a local and general effect upon the Vine.—NON-BELIEVER.

I FEEL much interested in the subject of Vines bleeding, and, like "Comber," have been anticipating something from Mr. Muir concerning the

scarcely amounted to "dropping," and has occurred when a cane or two of Black Hamburg has been planted with late varieties. The pruning that has been early enough for the late varieties has been a little too late for Black Hamburgs. The beginning of February is too late for pruning Vines; the sooner they are pruned in the new year the better. There is nothing gained by leaving them till later. If Vines are pruned early there is no need to use styptic, in fact it is simply a waste of labour. If "Comber" prunes a fortnight or three weeks earlier another season I think he will find that no bleeding will follow.—E. BUTTS.

CLIANTHUS DAMPIERI.

To a correspondent who seeks information on the culture of Clianthus we commend the following article by Mr. G. Abbey; it may also possibly be careful to others who desire to cultivate this gorgeous flowering greenhouse plant. Now and then we see a plant of this, but rarely a well-grown specimen:—No finer subject (if indeed any can vie with it among greenhouse plants) is found among the Leguminosæ. Its quaint flowers, 3 to 4 inches in length, are borne in clusters four to seven in

number upon a rather stout erect stem; they depend gracefully, are of a fiery scarlet colour, with a glossy deep bluish-black centre or boss, which seen amid or above the elegant light shining glaucous-green foliage have quite a striking effect.

Everybody of course knows that it is a native of Australia, and generally accepts it with *C. puniceus* as a climber. None of the plants I have grown of *C. Dampieri* are any climbing tendency. The first shoot, it is

true, rises erect, but is not long ere it seeks a dependent habit, and from the neck or collar of the plant emanate shoots about the same time as the primary growths begin to depend, and those have not an upward tendency. This habit is so decided that I can imagine no finer subject planted upon a knoll or raised bed with the shoots allowed to ramble at their own "sweet will" in all directions. The trusses of flowers will rise 4 to 6 inches clear of the foliage, appearing as jewels of coral set in silver. Or grown in a large deep pot raised so as to be level with the eye, the shoots depending all around would be when in flower strikingly effective.

The seed is sown early in June and placed in a hotbed, covering the seed about a quarter of an inch deep, the compost consisting of turfy loam three parts, sandy peat one part, leaf soil a part, half a part charcoal in sizes from a pea to a hazel nut, and half a part of silver sand, the loam and peat broken up rather roughly, the whole well incorporated. No difference is made in the compost afterwards, only old cow dung supplants the leaf soil at all subsequent pottings, and in case of the loam not being fibrous, equal parts of it and peat are taken. The seeds are placed two in a 4-inch pot, or several in a 6-inch, but the latter is not so good as the former, as the plants have to be potted off, which checks them considerably. So soon as the seedlings appear they are raised on an inverted pot near to the glass, the object being to keep the plants from drawing, especially the stem beneath the first leaves. Water is given sparingly, and always just within the rim of the pot, it being only given when the soil becomes dry. The pots are afterwards placed upon slates, as when stood upon soil the roots speedily find their way into it through the drainage. One crock and a lump of charcoal are employed for drainage. Shade is given the young plants after potting them, but when established they are fully exposed to the sun. Only one plant is grown in a pot, and with a genial atmosphere they grow freely. In a cold, moist, stagnant atmosphere they will not thrive, and drip upon their branches will destroy them.

When the roots show at the bottom of the pots shift into 7-inch, keeping well up in the centre and forming a dish all round just within the rim, using charcoal as before for drainage. If moderately moist when shifted, the soil employed being also moist, do not water after potting but wait a while, returning the plants to the frame. Never water until the soil be dry, and yet before the plants show distress, for this plant will not thrive in a parched soil. Red spider will come in due time, destroy it at the onset. Lay the plant on its side, syringe on the under side of the foliage forcibly, turning round so as to dislodge the enemy from every part. It must be done without deluging the soil with water, making it a quagmire. Repeat the syringing if necessary.

From 7-inch transfer to 11-inch pots, leaving space all around just within the rim (with the plant rather high in the centre) for watering. The drainage should be thorough—a fourth the depth of the pots. Pot moderately firm in compost rough rather than fine. Place in a pit or house, light, moderately airy, with plenty of room, having a temperature of 45° to 50° at night, 55° to 60° by day, or that of an intermediate house, mine being kept in a pit up to the end of September and then transferred to a greenhouse with a temperature from fire heat of 45° to 40° at night, 50° by day, but that temperature is too low. Notwithstanding, blooming commences in April and is continued until June. I have transerred plants from 4-inch to 9-inch pots successfully, but those who can command a position for planting out in a house with a winter temperature of 50° would, I feel certain, be amply rewarded by increased size of plant and bloom. I have sown in April and grown the plants in frames, but

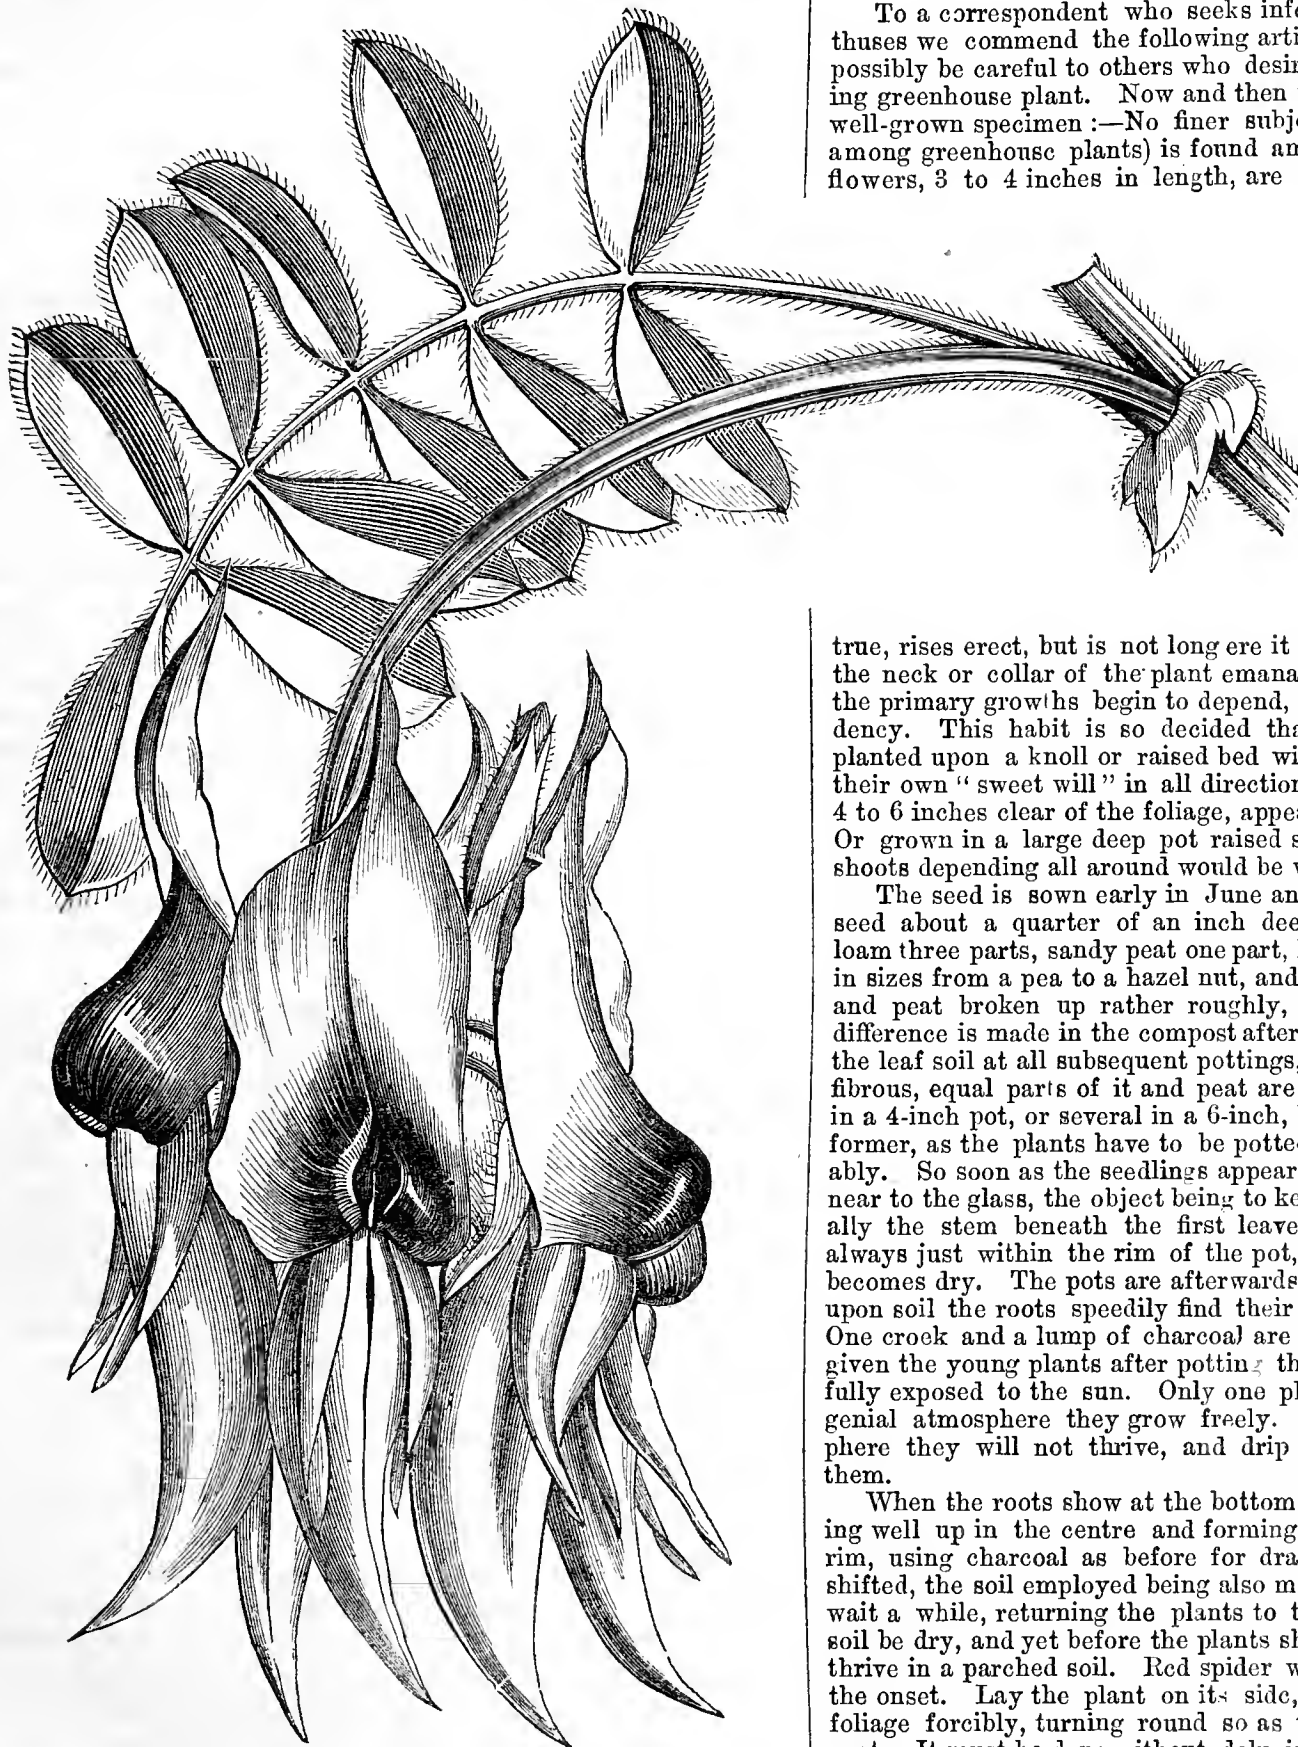

Fig. 13.—*Clianthus Dampieri*.

Vine mentioned in the Journal of April 5th, 1883. Some modern writers on the Vine seem to think it a matter of no importance, while others who give practical hints on Vine-growing advise the use of a styptic to prevent bleeding. In one large private garden in the midlands where I served as foreman, in one of our early houses a pot Vine commenced to bleed soon after being placed in heat. We endeavoured to stop the bleeding by searing the wound with a red-hot iron and applying styptic, then sealing wax. Both these failed, and the Vine continued to bleed till it had made shoots 2 or 3 inches long. The shoots were weak and the Vine was in every way inferior to the others in the house. The only inference we could draw was that the ill condition of this one was the result of excessive bleeding. The case of "Comber's" Vines is singular. I have occasionally seen a Vine or two bleed slightly and then cease, but in such cases it has

being large in autumn did not winter well, as flower trusses were shown in early winter, which in a temperature of 45° to 40° at night and 50° by day did not advance.

The plants are very impatient of a wet sodden soil, and equally so of a cold damp atmosphere, but they flourish in a brisk moist heat if ventilated freely and not shaded. Sown the middle of August in a hotbed in 4-inch pots, removed to a house with a temperature in winter of 45° to 50°, given 7-inch pots the end of September, 9 or 11-inch in February, we have plants that flower in June through the summer.

As to training, let its shoots come out naturally, for it is ill-suited for twisting round stakes; but if stakes must be used employ as few as possible, not distorting by seeking to make it climb, which is contrary to its nature. The annexed figure of a spray of this plant will enable those who are not yet acquainted with it to judge of its appearance. Although very old the plant has not yet been seen by everyone.

[Messrs. Carter & Co. have been very successful in growing this plant in their nurseries at Perry Hill. • The plants were, as Mr. Abbey suggests, grown on a "knoll or raised bed;" but the mounds were formed in a low span-roofed house, and the shoots were secured to the lower part of the roof. The rich pendent flowers were thus seen to great advantage, and some of them exhibited at a meeting of the Royal Horticultural Society secured for the growers a cultural commendation. We have never seen such a fine example of culture in a pot as on the knoll referred in the light greenhouse at Perry Hill.]

CHATSWORTH.—The following announcement, "We understand that Mr. Thomas Bannerman, gardener to Lord Bagot, Blithfield, Rugeley, has been engaged by the Duke of Devonshire to succeed the late Mr. Speed as gardener at Chatsworth" appeared in the *Gardeners' Chronicle* last week, and brought us telegrams and letters controverting its accuracy. We are in a position to say that the statement is incorrect. Mr. Bannerman, in a letter before us, himself denies its truth; and the Duke of Devonshire's agent informs us "that a gardener has not been appointed for Chatsworth, and it is not expected that the appointment will be made for some little time."

— MR. J. DOUGLAS writes:—"D., *Deal*," writing at page 58, states that £243 was given for a plant of *Vanda Sanderiana*. This is incorrect; it was for a plant of *AERIDES LAWRENCIÆ*, quite a unique specimen, of which it was presumed none like it would ever be introduced. The trade in Orchids is now becoming so extensive that nurserymen and amateurs are getting sadly mixed. I do not allude to this particular plant. Of its destination I know nothing. But it seems to me that where a person can go into a garden and purchase plants at the usual retail or wholesale price that garden cannot be considered other than a nursery. Amateurs purchase in many cases with the intention of selling again. I do not know whether all this is fair to the heavily taxed nurseryman. I believe the sale of that plant cost Mr. Sanders a special visit of the tax-gatherer, and a grievous addition to his already heavily taxed business."

— THE same correspondent also observes with regard to PRICES OF TULIPS:—"At page 66 it is stated that certain Tulips were sold in 1854 at one hundred guineas each. This statement is also made in my book on 'Hardy Florists' Flowers,' but I am not sure whether it is quite correct, and in another edition of the book it would be modified. The reason I arrive at such a conclusion is this: In 1854 Mr. Groom catalogued show Tulips at the prices given in my book, and quoted correctly by Mr. Robinson. We have no positive proof that he sold any of them. And I am the more confirmed in this belief because on the 30th of October, 1855, Mr. Groom's Tulips were put under the hammer of Messrs. Protheroe & Morris, and the highest price obtained for one row of seven roots was 60s., not 9s. each."

— MR. W. BARDNEY writes as follows concerning READ'S NEW HEARTING BORECOLE—"It is dwarf, the leaves are beautifully curled, and I would recommend those who grow Borecoles to give this variety a trial. It is said to be perfectly hardy, and I should say such is the case judging from the quantities that I have seen in the Liverpool market late in the season during the past five or six years. It is also said to

remain in good condition after all other Borecoles have commenced running to seed. This I believe will prove the case, for those alluded to have come to the market in good condition long after the varieties of dwarf curled have been running freely to seed with me. I have tried several times to obtain the seed of the variety sent to the market, but failed to do so. Are there two varieties under this name? If so, can anyone point out the difference between them?

— "M. S." considers that *IRIS STYLOSA* or *UNGUICULARIS* should be grown in all gardens. No doubt the exceedingly mild weather has had something to do with its earliness in flowering this season, but in ordinary winters unprotected in the open border it is seldom a fortnight later than this. It is much like *I. fimbriata* and *I. Robinsoniana* in general appearance.

— IN the note on POTATO TRIALS AT CHISWICK, which appeared at page 62 of our last issue, a clerical error (for which we are not responsible) occurred. Instead of "six fair samples of each," the reading should be "twenty fair samples," and not more than eight varieties.

— AN unusually fine display of ORCHIDS IN FLOWER was provided at Messrs. Protheroe & Morris's monthly sale in their rooms, 67 and 68, Cheapside, on Tuesday last. It was indeed quite an exhibition, and attracted a large number of buyers and admirers of Orchids. *Odontoglossums*, *Cœlogynes*, *Cypripediums*, *Dendrobiums*, *Lælias*, *Lycastes*, *Sophronitis*, and many others were represented by scores of plants, mostly flowering very freely. The principal prices realised were the following:—*Odontoglossum nobile cærulescens*, 8 guineas; *O. Andersonianum*, 9½ guineas; *Lælia anceps*, good variety, 10 guineas; *Oncidium superbiens* var. *Enoi*, 18 guineas; *Lycaste Skinneri alba*, 21 guineas; *Odontoglossum crispum* var. *Dormanianum*, 8½ guineas; *Epidendrum Wallisi*, 19 guineas; *Odontoglossum Alexandræ*, very fine variety, 15 guineas; *Dendrobium Ainsworthi*, £6 and £5 10s.; *Cœlogyne cristata*, £8 10s., very large, over 3 feet in diameter, and in fine condition; and *Cypripedium villosum*, a very large specimen, 3½ feet in diameter, with thirty-five flowers, £5.

— WE are informed that the dates for the BRIGHTON AND HOVE CHRYSANTHEMUM SOCIETY'S SHOW for this year are fixed for the 11th and 12th of November next. The Secretary is Mr. Mark Longhurst, 87, Western Road, Brighton.

— THE fortnightly meeting of the Manchester Horticultural Mutual Improvement Society was held at the old Town Hall, King Street, on Thursday evening, when Mr. Bruce Findlay read a paper on the DISEASES AND CASUALTIES OF VEGETABLE LIFE. Mr. Frank Robinson presided, and there was a large attendance of members. Mr. Findlay said that he had been induced to turn his attention to the subject by the quack advertisements which promised to cure all manner of diseases to which animal and vegetable life were subject. It behoved them to be on their guard against quacks. He did not mean to insinuate that all the advertised curatives did no good, for he knew that the contrary was the case with many of them. He divided casualties under three heads—namely, wounds, diseases, and natural decay. Touching upon the felling of trees, which seemed to be a favourite occupation and pastime of many eminent men, he remarked that the practice was to be deprecated unless it was necessary. Looking around Manchester, a man who had known it for half a century could not fail to see the powerful pestilential agencies at work which had killed trees by thousands, but seldom did we see any planting done. Our municipal authority lavished a great deal of money upon art galleries and in other ways, against which he had nothing to say, but it would be thought suicidal to spend £4000 or £5000 upon the planting of trees. He contended that a man who caused a tree to grow in a town raised the most beautiful monument possible. We should, therefore, do what we could to put a stop to the practice of cutting down trees for mere pastime. The most frequent diseases of vegetable life were the following—Blight, smut, mildew, honeydew, dropsy, flux of juices, gangrene, suffocation, contortion, and consumption. He explained the nature of each complaint, and then spoke of natural decay, which formed the last section of the paper. Mr. Williamson of Whalley House afterwards exhibited some splendid blooms of Japanese varieties of Chrysanthemums.

— IN reference to FLOWER FARMING IN NEW YORK the following recently appeared in the *New York Times*:—"The sale room is that of one of the largest commission dealers in flowers in New York. 'I want fifty Jacs,' said an elderly gentleman with a capacious basket who had come for his daily supply, 'a dozen Mermets, 100 sprays of Mignonette,

200 Carnations, 200 Camellias, fifty strings of Smilax, twenty-five Lilies of the Valley, and fifty Bouvardias.' The articles were counted off as he named them and put into the basket; the wholesale price of the order was £16. The basket would easily hold £100 worth of Roses or £200 worth even of Lilac sprays, which at this season of the year are among the most valuable of flowers. 'Until ten years ago,' explained the commission dealer, 'the flower-growers sold their stock to the florists direct; but with the growth of the business there became a necessity for middlemen, and now nearly the entire merchantable stock of flowers used in New York passes through the brokers' hands. The business of growing fine flowers for the market has become a great industry; hundreds of thousands of dollars are invested in hothouses, and the product amounts to over £400,000 a year at the wholesale prices. There are over 500 men engaged in the business, many of whom are millionaires who have made the profit on their gardens pay the expenses of their places and a handsome interest on the money besides. Flowers now are as staple article as Wheat or corn. A good Rose bud is always saleable for cash. This morning we had 20,000 Rose buds on our counters, and every one is sold, and half as many more could have been disposed of if we had them here.'"

— THE Hon. Secretary of the PERSHORE HORTICULTURAL ASSOCIATION (Mr. J. Milward) reports that the banking account of the Association shows a balance in their favour of about £360, and that to witness the show and sports on Bank Holiday, 6th August last, when rain fell in torrents during the greater part of the afternoon, upwards of 10,000 persons were admitted.

— "WE greatly doubt," observes the *Irish Farmers' Gazette*, "if anywhere else is to be found a more extensive or more interesting series of HELLEBORES than are to be found AT GLASNEVIN, not only in the way of species and established varieties, but notably in the several novel and beautiful forms originated there by hybridisation, and now developing their colours and character. Mr. Moore is following up the work, and at the present moment has a large number of seedlings from last year's crossing and seed-saving."

— In a Hand Guide to the CEYLON BOTANIC GARDENS recently issued by Dr. Trimen the following interesting particulars are given:—"The Royal Botanic Gardens at Peradeniya were established in 1821, six years after the final occupation of the Kandyan Kingdom by the English. The site is less than four miles from Kandy on the Colombo road, and occupies a loop of the river Mahaweli, which surrounds it on all sides except the south, where it is bounded by the high road. The area, nearly 150 acres in extent, is beautifully undulated, its average elevation above sea level being about 1540 feet. The climate is hot, moist, and very equable; the mean annual temperature is about 77° F., April and May being the hottest and December the coldest months. Rain falls on about 200 days in the year, the annual rainfall being about 85 inches; it is pretty evenly spread through the year, but is heaviest in October and November and in June, at the full establishment of the N. E. and S. W. monsoon, respectively. February and March are the driest months, but even then there are showers at no distant intervals. Before its occupation as a Botanic Garden the greater part of the land had been a royal demesne occasionally occupied as a residence by the Kings of Kandy. The earth-mound and ditch along the south boundary are still evident, and remains of stone buildings have been found. The name *Péra*, Guava, and *deniya*, an enclosed place—indicates its use as a fruit garden of which the existence of some very old Mango trees is further evidence. On another part of the site stood a small temple or flower shrine and priest's house, abandoned, however, before the formation of the garden. This garden now contains considerably over 2000 species of plants. The Director has also under his charge, as adjuncts to the Peradeniya Gardens, smaller branch establishments in different climatic districts of Ceylon. Hakgala Gardens are situated at an elevation of 5500 feet about six miles to the east of Nuwara Eliya on the road to Badulla. They were opened in 1860 as a Cinchona nursery. The climate admits of the cultivation there of numerous European and Australian plants, and those of the tropical mountain regions. Henaratgoda Garden is a completely tropical one, scarcely above sea level, and in a wet steaming climate which varies little. It is about three-quarters of a mile from the railway station of the same name on the Colombo-Kandy railway. Many of the plants grown at Peradeniya flourish there with far greater luxuriance, and others can be cultivated there only. It was opened in 1876. Anuradhapura Garden. —This is in process of formation at the ancient capital of Ceylon, ninety

miles north of Kandy (seventy-four from Matale), in a district which possesses a hot dry climate with a short rainy season, like the Carnatic or Coromandel Coast. Here such plants and crops as are intolerant of continuous and excessive moisture can be cultivated."

CHRYSANTHEMUM LORD ALCESTER.

I DESIRE to state that the above-named variety is identical with my Princess Imperial, which I exhibited in an undeveloped form at the Westminster Aquarium in November, 1882.

Mr. Wills procured a young plant from me last spring, from which he obtained the magnificent blooms exhibited by him in November, 1883, at Southampton and Kingston-on-Thames, for which he obtained first-class certificates. Had I been consulted I should have preferred its retaining its original name. Be it understood, I am not writing in a spirit of antagonism to Mr. Wills. He will share equally with me in the proceeds; but in fairness to others who purchased plants of me, and who are, as yet, unaware of the change of name, I feel bound to make this explanation.

It was arranged between Mr. Wills and myself that he should do the selling, but as I hold the stock, and he was unwilling to make the necessary explanation, I have decided to take the orders and execute them direct as per advertisement. — HENRY FREEMANTLE, *Bishop's Hull Taunton.*

P.S.—Princess Imperial, *alias* Lord Alcester, is a sport from Empress of India, and was raised by me five years ago.—H. F.

CONTROVERSY.

WHEN the writer was a learner he was for several years connected with debating societies in a town, and had good opportunities of coming in contact with young men with better opportunities and better educated than himself, and he looks back to that time as a very agreeable period of his life, when he learned much that has been of great service to him since. At one debating club which he attended twice a week the debates were often very keen, and one of the most formidable disputants was a young student, now a Scottish parish minister, who was a terrible catechist more than anything else, and whose "whys" and "wherefores" and habit of probing opponents' theories to their source caused him to be regarded with great deference and circumspection by the rasher and more speculative minds after two or three encounters with him. Well, this young student gave the writer this excellent advice in the following or similar words:—"Strive," he said, "to get an accurate knowledge of your subject, and whether speaking or writing never advance anything confidently, or as a fact, which you are not sure about. On the other hand always drive at the foundation of your opponent's argument, as if you can find a flaw in his premisses you are far more likely to defeat him there than by wrangling over side-issues, which tend to confuse debate; press him for reasons and proofs, and probe him closely on all vital points. If your opponent be a reasonable man he will be only too glad to satisfy you, and you will probably learn something; if he is not a man of this stamp the probability is he will lose his temper, and perhaps become abusive and mount the 'high horse,' but if you stick to him he will have to give way in the end—at all events he will be silenced if he has any sense. A man who persists in mere dogmatic assertion is not worth arguing with."

These remarks have been suggested by the controverted articles in the Journal lately. It is admitted by scholars that among ordinary writers and speakers on the various subjects that interest mankind, a very small proportion only know how to state their case logically, and fewer still know what "demonstration" means. It may be seen in our gardening papers often enough that writers as a rule set out by taking something—their premisses—for granted, quite wrongly perhaps, and on this foundation they proceed to build some hypothesis or other, and from it to draw false conclusions that only widen the area of error. Much needless space, too, is occupied, as anyone can see, by writers not correctly apprehending what they read, and not being able to state clearly what they think themselves; and this takes no account of those numerous communications which are passed into the wastebasket by editors, but which they would no doubt be glad to publish if they could see their way to do so. As an example of the aimless questions sometimes put, and supposed by the questioner to be full of significance, I may refer to one put lately by a correspondent, who desired to know in connection with stored-up sap where the young shoots derived their sustenance from that grew upon Vine wood that had been bottled to preserve the Grapes upon it. Had this writer asked himself why he put the shoots with the Grapes upon them in the bottles of water and other ingredients, in the first instance, he need not have asked such a question.—CASUAL.

VINE ECONOMY.

ABOUT New Year's day, 1882, several large Oak trees growing on a steep hillside near here were uprooted by the wind, and fell with their tops directly down the hill. Nearly all the roots were severed; a few might have escaped with a severe wrench. The ball of earth torn up with them was very small. They burst into leaf as usual, and remained green about the usual time; but they made no growth, except one of them, at the top, which was now the lowest part of the tree. There, on the points of what had been the highest branches, I was surprised to see watery shoots of from 12 to 16 inches long, bearing leaves nearly as large as my hand, or three times the size of the others. The place was

shaded and the summer a wet one, but I would like to hear it further explained.

Although I agree with Mr. Taylor as to Vines storing sap, I cannot agree with him as to the very peculiar economy of that plant. The Willow, Bird Cherry, and other trees and shrubs will strike root from either end with almost equal readiness. If Vines do subsist almost equally on bare rocks and decayed horseflesh they are very peculiar, but perhaps that power their roots possess of penetrating solid masonry may enable them to extract something out of rocks also. The Oaks I have already mentioned made leaf-growth with very little, probably with no root-growth at all. Many hardwooded trees (Elms, for instance), send out roots to long distances and through what appear to be very uncongenial substances. I once saw a rope-like mass of fibres 6 or 7 feet long taken from inside a lead water pipe, where it had originally penetrated through a very small hole. I think it was Elm, but am not quite certain. Most fruits drop off when they reach maturity. Probably if they were, like the Grape, persistent, putting the branch on which they grew in water might preserve them in the same way.

Anyone wishing to find an instance of stored-up sap becoming liquid at the approach of spring has only to cut a few Potatoes two or three weeks after this. They will be found to be unusually juicy, and to my taste have a particularly fine flavour when cooked. I believe sap is stored up in the Vine and deciduous trees, shrubs, and climbers in the same way.—DUGALD.

HARDY PLANTS AND THEIR SYNONYMS.

Of late many complaints have been made anent the difficulty of procuring plants true to name from nurserymen, and as a step in the matter I have recorded many of the most striking and most common synonyms for the benefit of those who have not a large collection, and therefore have not the opportunities of identifying the plants. The nomenclature adopted is that employed at Kew, and if taken up by cultivators will no doubt be the dawn of a system, when confidence in the general naming will invite exchange without reserve. The following list includes only a few of the principal examples, and might be profitably supplemented by your correspondents as experience enables them.

PAST v. PRESENT WRITERS.

ADVICE TO YOUNG GARDENERS.

WITH your permission I would like to make a few remarks on the numerous letters which I have had much pleasure in reading in your columns the last few weeks. I was pleased to see that my "Word to Young Gardeners" was the means of drawing one of the old school from his shell, and I must thank him for his flattering words of approval. At the same time I would suggest that he has not made himself fully understood.

Thirty years ago young gardeners were not so numerous as they are now. Much of this increase has taken place in the neighbourhood of our large towns. To these centres many of our young men from the country find their way when comparatively inexperienced in their business, as they must of necessity be of town social life and manners. The great majority in search of fresh places find their way into some of our large nurseries. A few months in one of these is by no means lost time. A slow youth will possibly get smartened up a little, a conceited one is very likely to get some of it taken out of him, and the steady observant youth will pick up many hints worth remembering. While so situated, or when in a gentleman's garden near a town, those who have a real love for gardening will profit by the change. They will visit all public parks and gardens, nurseries and private places of interest, and always be adding to their store of knowledge.

On the other hand, those who have no particular interest in their business will rush here and there after "wonderments," and they will generally find plenty of companions ready to lead the way into all sorts of temptations entirely new to our young man, and if he is fascinated with them he may go on wasting his time, his hard-earned wage, and acquiring habits that will be difficult to shake off if too long indulged in. Such men when sent to an out-of-the way country place are very apt to make a speedy return to the same or some other

nursery, and so they get into that unsettled state that they make but little progress, and are often a continual source of anxiety to their employers. I am afraid it is by such men that "H., Notts," has judged young men as a whole; but I hope when the more intelligent class is placed in the balance with them that the result would not be unfavourable to the latter.

Some time ago I went with a neighbour to see a friend at some little distance from home. In the course of our conversation our friend remarked that he had had a call of two young men from such a place near us a short time before. "Oh!" exclaimed my neighbour, "why those two Scotch fellows have been to every place within twenty miles." Now I think these are the sort of "fellows" to get on; and I think this cultivating the acquaintance of other gardeners and seeing their gardens as a means of improvement should be encouraged.

I must thank, may I say, our Chaplain for his timely support in his new year's address. May his words be taken more seriously to heart by "A Young Gardener" and "T. L." than they are inclined to look upon the advice offered by myself. I am sorry that my letter, in the ideas of these two young men, savoured so much of the "lecturing" or "preaching" style. "A Young Gardener" so links my humble advice and the remarks of "H., Notts," together, that it would lead your readers to believe we had made a united sweeping condemnation of all pleasure for young gardeners. This is not quite in accordance with facts. My "lecture" was directed against going to extremes—as I unfortunately did myself in some matters—rather than to the discouragement of all relaxation. I like music, and dancing too, and like to see young men acquit themselves creditably in the social circle on occasions when little accomplishments and good manners are expected to shine. The danger is when fascinating pastimes are allowed too much scope. There are men, and young men too, who can take these things, but there are others who cannot; and when, as is often the case, young men take to continually scraping on a fiddle, strumming on a concertina or dancing, and singing tap-room songs, woe be to all within hearing of such. If young men have an ear for music, let it be devoted to something more elevating than that. Let them learn to read music and practise part singing, and they will have a never-failing source of pleasure, either in company of their fellow men, or if in some lonely country place where but few opportunities of intercourse with the outer world occur. I hope "A Young Gardener" is one of those who can take things in moderation, and that he does not too frequently feel disinclined "for harder studies."—A WORKING GARDENER.

THIS subject has been the means of raising a somewhat lively discussion in the Journal, and is one in which all who care for the future of gardening should take an interest. Though not disposed to side entirely with either of those who have been contending in the matter, the writer would admit at once that there is truth on both sides. There are men of the present day who do not come up to the standard of many of those of past years, but at the same time there are numbers of young men who give promise of being at least equal to any of those who have preceded them. The numbers that now are following the gardening profession greatly exceed former days, consequently among so many there is not much difficulty in picking out instances of bad conduct, want of application, and disregard of the study required to enable a man to become a credit to his calling. But there can also be numerous cases of diligent study and exemplary conduct pointed out, and when such is the case there cannot be much fear of the gardening profession retrograding so much as some would assert.

No doubt there are many young gardeners who have not very many advantages, and who avail themselves to the utmost of what they have; and on the other hand there are some who, though favoured with many opportunities for self-improvement, wilfully neglect them. Bothy life now-a-days is, as a rule, much more comfortable than it was thirty or forty years ago, and the wants of the young men are undoubtedly more fully supplied now than then.

There is one evil of the present day that sometimes causes much annoyance—that is, when masters give good characters to men who in reality are not deserving them. Mutual confidence between head gardeners is sometimes much endangered by this evil. No doubt it happens through kindness, and full allowance must be made. But a little wholesome truth sometimes would be the means of not only preventing another employer being deceived, but also of making the young man endeavour to mend his ways. "Honesty is the best policy," applies with equal force in things relating to gardening and gardeners as it does to any other walk in life, and all should endeavour to proceed on thoroughly honest principles.

That gardening is a most difficult and complex study must be admitted, so much the more necessary is it that young men devoting themselves to it should use every means in their power to attain to the highest position. A kindly feeling between head and under gardeners must in all cases go a long way towards making young men take more interest in their calling. That this feeling exists in most cases is pretty certain. The advice to not only read a gardening periodical, but also to obtain, bind, and preserve for reference, is sound, and should be followed by all. There can hardly be a case now-a-days where a man cannot afford to do this. There is some little thing he can dispense with in order that a periodical may be taken. Some good is derived from reading papers at meetings, but not so much, I think, as others seem to imagine. There is a little danger of young men thinking themselves much more clever than they really are after they have contributed a paper or two to these meetings. Continual and intelligent observation of all going on around

copious notes, careful reading and thinking over all articles in the periodical they take, will help much more to improve men than an occasional paper read at a meeting, if such is not combined with steady and judicious study.

Books on botany and gardening subjects can be obtained at cheap rates now, and should be acquired as soon as funds permit. Knowledge gained and properly stored in the mind is always of service.

"Thus useful arms in magazines we place,
All ranged in order, and disposed with grace;
Nor thus alone the curious eye to please,
But to be found, when need requires—with ease."

—VITIS.

[A letter from our able correspondent and valued old contributor, "H., Notts," will appear in a future issue. He has a good and good-humoured word for all, and an excellent retort for most who have pressed him rather closely in the discussion which he raised.]

CACTACEOUS PLANTS.

(Continued from page 42.)

GENERAL CULTURE.

THE numerous members of the Cactus family are exposed to widely differing temperatures in their native habitats, owing to the extent of the American continent over which they are distributed, but also to the great elevations on the mountains of those regions at which some are found, and it is principally in regard to heat that the treatment of Cacti has to be varied. A large number, probably the majority of known species, frequent the desert-like plains and the rocky volcanic districts of Chili and Mexico, where they grow and flower under the fiercest tropical heat, not only uninjured, but positively luxuriating in their strange fashion in the burning rays of an unclouded sun. There for the greater portion of the year the soil is parched, and the atmosphere suffocatingly dry, and no other plants can exist except those which have become adapted to the peculiar conditions of the climate, either resembling their Cactus neighbours in developing a succulent growth containing an abundant store of fluid support, or possessing foliage protected by a thick impervious leather-like epidermis, which effectually enables them to withstand the rapid evaporation constantly proceeding in such regions. It is not easy to exactly reproduce these conditions artificially when cultivating the plants in our northern climate; we can, however, insure a sufficiently high temperature with the requisite aridity of soil or atmosphere, and this seems all that is needed, though undoubtedly the maturing effect of a roasting sun is missed to some extent. For these really tropical Cacti a special house is required to give the cultivator an opportunity of growing them to the best advantage, as when included in a mixed collection of plants they are usually exposed to a much greater humidity than is beneficial to them, and they consequently flower less freely. This applies especially to the majority of the Echinocactuses, Melocactuses, Opuntias, and Cereuses, though in the latter genus there are several exceptions, as some species require the moist atmosphere of an ordinary stove. Nearly all the family need a free exposure to the sun; but even amongst the tropical species there are exceptions to this rule, for the Rhipsalises and Epiphyllums, being epiphytal in habit, succeed best in moderate shade, and can indeed be associated with such moisture-loving plants as Orchids and Ferns.

In ascending the mountains of central and northern America, where the Cacti abound, some of the wandering species of most of the genera are found similarly happy in much lower temperatures, until at an altitude of 8 to 10,000 feet in the Rocky Mountains some Opuntias and Echinocactuses still form a portion of the vegetation, and are frequently exposed to frosts and snow. It will thus be seen that in a broad sense the Cacti may for cultural purposes be divided into three groups:—1st, the tropical species from the lowlands and plains, extending for a short distance up the mountains; 2nd, the intermediate species, which are found on the extreme northern limits of their distribution, and which rise to a considerable height in the mountains, but still below the frost line; and 3rd, those which inhabit the highest elevations. The two first would respectively require the temperature of a dry stove and a greenhouse, while the remaining group includes those which have been found to be hardy in England.

Except where very large collections are formed and every effort is made to imitate the natural conditions, houses cannot be specially devoted to each of the two former groups, and the Cacti are so extremely accommodating that they will apparently conform themselves to any reasonable treatment. Wherever these plants are made a speciality one house at least can be appropriated to them, and this is really all that is necessary, for the species from the tropical regions can be placed at the warmest end, the intermediate and cool species being accommodated in different positions according to the varying temperature. A third class of cultivators, however, and by far the largest, are those who grow a moderate collection as examples of the most curious phase of vegetable life, and who cannot give them special quarters, being compelled to grow them with other plants. In this case the best general plan to adopt is to give the plants cool and dry treatment during the winter, a greenhouse or conservatory being a suitable place; while in the spring and summer, when growth is made, a heated frame facing south is admirably adapted for them, as there they can be arranged near the glass, fully exposed to the sun, and provided with sufficient moisture to stimulate growth without rendering it weak. The last method is an excellent one, even where the largest collections are grown, and I have obtained better results by so treating them than by any other method. Some, indeed

place the plants outside in a sunny position during the summer, but in our uncertain climate this is attended by many disadvantages, for they are liable to be much injured by sudden storms of rain or wind, and the varying temperature alternately accelerates and checks the growth, which consequently rarely becomes properly matured, and the delicate species are often irrecoverably damaged. On the continent, where the summer climate is more regular and the sun power greater, the case is quite different, and the practice is attended with proportionate success.

The cottager and others who grow their small collections of Cacti in rooms must necessarily confine their attention to comparatively few species and varieties, but it is surprising how much pleasure and interest may be obtained from even such modest efforts as these. A table or shelf near a window is the position usually assigned to them, and under the circumstances it is the best they could have, as the plants are well exposed to light, they are surrounded by a dry atmosphere, and they are safe from frost. If in addition to these matters the plants are accorded a moderate share of attention in regard to the supply of water, there are very few of the Cactus family that will not thrive and occasionally flower. The *Cereuses*, *Opuntias*, *Echinocactuses*, and *Mamillarias* can all be so grown, but if a glass case can be provided for the smaller and more delicate kinds, it will be advantageous in protecting them from the dust and smuts that so soon accumulate in rooms, and which cling to the spines and surface of the stems, effectually spoiling their appearance and preventing their progress. Such cases can be readily constructed, or they can be purchased ready made, as several firms now sell them for the miniature Cacti that have obtained a good share of popularity during recent years. These miniature plants are particularly well adapted for rooms, and in their bright red diminutive pots have a very lively appearance. They are sold, too, at such moderate prices that they are within the reach of all. As room plants indeed the Cacti are unexcelled, for though they do not possess the brilliant and profuse flowers of *Pelargoniums* and other ordinary softwooded plants, they never bear the sickly and miserable aspect that such too often do when they have been long grown indoors. I would by no means advocate the exclusion of the ordinary popular window plants, but as a reserve force the Cacti are invaluable.

MAMILLARIA, HAWORTH.

It would be very difficult to find any plants in the whole vegetable kingdom which present such beautiful examples of symmetry as the *Mammillarias*, and in their own family they are also unique in this respect, for though many of the grotesque *Opuntias*, *Cereuses*, and *Echinocactuses* possess larger and more brilliant flowers, and they are surpassed in horticultural value by the *Phyllocactuses* and *Epiphyllums*, yet for delicacy of design they are unrivalled. A large number of them resemble exquisite pieces of mechanism finished with the greatest minuteness and accuracy. Others, again, might be imagined to have undergone a kind of crystallisation, their whole surface being frosted over with star-like spiculae arranged with geometrical precision; and still others appear as if covered with the finest gossamer. The graphic remarks of Dr. Lindley which accompanied the figure of *M. tenuis* in the "Botanical Register" in 1832 might well be applied to several species with even more accuracy than in that case:—"Gentle reader, hast thou never seen in a display of fireworks a crowd of wheels all in motion at once, crossing and intersecting each other in every direction, and canst thou fancy those wheels arrested in their motion by some magic power, their rays retained, but their fires extinguished and their brightness gone. Then mayst thou conceive the curious beauty of this little herb, a plant so unlike all others that we would fain believe it the re-animated spirit of a race that flourished in former ages with those hideous monsters whose bones alone remain to tell the history of their existence in the quarries of our sandstone, slate, and clay." Strangely beautiful indeed are most of the *Mamillarias*, and in contrast with their neat rosettes or stars of spines are the rosy, yellow, and white flowers, which are generally followed by small berry-like coral-coloured fruits, that, dotted amongst the spines, add another phase to the attractions of these plants. With so much to recommend them it is not surprising that they have become great favourites with cultivators of Cacti, and with that portion of the public who have obtained any knowledge of them.

The genus *Mamillaria* was founded by Haworth upon the Cactus *Mammillaris* of Linnæus, one of the oldest cultivated species, and this was re-named by the first-mentioned author *M. simplex*. Two others were associated with—viz., *M. prolifera* and *M. discolor*, which at that time, 1819, were all that were known. Since then, however, the number of described species has been increased to 300, which abound in Mexico, the head quarters of the genus, some being also found in the West Indies, Brazil, and Bolivia, their habitats and the elevation at which they are found varying considerably. In characters of flowers and fruit the *Mamillarias* resemble several other genera, but the chief distinguishing mark is found in the mamillæ, papillæ, or tubercles from which the plants derive their name. The stem is cylindrical, globular, or conical, seldom exceeding 10 or 12 inches high under cultivation, and more frequently only 3 to 6 inches high and 1 to 3 inches in diameter. From this axis arise the teat-like projection termed the mamillæ, but for which the word tubercle is here adopted. These vary in size from minute elevations scarcely a sixteenth of an inch high to some 1 inch high and as much in diameter; in form they also vary, from cylindrical, spindle-shape, conical, or ovoid to angular and irregularly pyramidal. They are arranged spirally round the stem with great regularity, and each bears at its apex a cluster of spines, often in two series, the outer white, very fine

and hair-like, from six to twenty, very closely set, and radiating laterally in a star-like manner, much resembling the pappus crowning the fruits of some plants in the Compositæ family; the inner series is usually composed of a few stiff spines, sometimes hooked at the points, and usually coloured differently from the others, being yellow, brown, red, or purplish.

The variations in these organs or appendages furnish the chief characters for distinguishing the species, and upon them some authors have constructed an elaborate system of classification in groups and sections. In Hooker and Benthams "Genera Plantarum," however, Engelmann's three subgenera *Eumamillaria*, *Coryphantha*, and *Anhalonium* are adopted for the main divisions. The first includes the majority of the species, which are characterised by the tubercles not being furrowed, and by the flowers being produced from the axils of the previous year's tubercles—that is, from the side of the stem. The second has furrowed tubercles, and the flowers produced from the apex of the stem or from the axils of the tubercle of that season's growth. The third was constituted a genus by Lemaire, but is regarded as inseparable from the *Mamillarias*, though in general appearance they are quite different, the tubercles in *Anhalonium* being spreading, thick, and leaf-like, somewhat after the style of the *Gasterias*.

Culture.—Many of the *Mamillarias* are found in limestone districts, and though inhabiting varying climates and elevations, they may be all grown in an intermediate temperature, such as a greenhouse, where they can be protected from frosts during the winter, but a higher temperature is needed during the spring and early summer when growth is advancing. A free exposure to light and sun is requisite at all times. The soil should consist of two-thirds sandy loam and one-third finely broken bricks and lime rubbish. The pots must be well drained, and water should always be carefully supplied, but much injury is often done by keeping the plants too dry. They should be examined at least once a week, even in the winter, and if the temperature is above 50° and the weather bright they may be safely watered. In colder quarters little will be needed during December and January. These plants may be advantageously grown in a glass case, as this protection keeps the dust from their beautiful spines.

Propagation.—The majority of the tufted and branching species can be readily increased, either by the offsets from the base, or by removing the side branchlets. The former only need potting like ordinary plants, keeping them rather dry until growth commences. The branchlets can be laid upon dry soil until some roots show at the base, and they can then be treated similarly. The more delicate sorts, or those that produce few offsets, can be grafted on any of the *Cerei*, to which they readily unite; and this has a double advantage, for while the plants often grow more strongly, they are also less liable to decay, as such forms will do unless very great care is exercised in supplying water. *Cereus tortuosus* and others of slender habit may be chosen for the small-growing species.

SELECT SPECIES.

M. ANGULARIS, *Hort. Berol.*—One of the more robust forms. The freely branching habit gives it a very distinct appearance, and when well grown it has a fine appearance. The largest specimen I have seen is in Mr. Peacock's collection, and is over a foot in diameter; in excellent health. Decandolle's *M. triacantha* and *M. cirrifera* of some gardens (not of Martius) have been regarded as varieties of this species, the last named corresponding to Salm's *M. angularis* var. *pulvenscens*. It can be readily increased by offsets. Introduced in 1835. Strong-growing; stem freely branched, 4 to 8 inches high, 2 inches in diameter; tubercles conical, thick, a quarter of an inch long, having a tuft of white down at the top, and four or five white spines of irregular length; flowers rosy purple.

M. BICOLOR, *Lehmann.*—The whole surface of this plant appears as if covered with a fine cobweb, owing to the numerous closely-set white hairs which form the outer series of spines; and if grown under a case or in a position where the dust can be excluded it is one of the most striking of the genus. Some crested forms of this are grown, but they possess little beauty, and are usually simply deformities. The species was introduced in 1835. Very distinct; stem cylindrical, somewhat club-shaped, 8 to 10 inches high, 2 to 3 inches in diameter, branching from near the base; tubercles very short, dark green, but hidden by the spines, which are in two series, the outer fine and hair-like, closely set, and spreading, the others being fewer, erect, and of a yellowish tint. The flowers are small and purple.

M. CAPUT-MEDUSÆ, *Otto.*—The Medusa's Head *Mamillaria* is by no means so formidable as its name implies, and though not so delicately beautiful as its neighbours it possesses a boldness that forms a striking contrast with them. A fine specimen, probably the largest in England, is included in the collection of these plants grown by Mr. Boller at the Wood Green Nurseries, Harrow Road, N., for which he has been awarded numerous first-class certificates at metropolitan and provincial shows. Stem usually 4 to 6 inches, or in exceptional cases 8 inches in height, globular or occasionally columnar; tubercles four-angled or ovate, bearing four small white spines and two thicker and stronger ones; flowers white, about 1 inch in diameter.

M. CIRRIFFERA, *Martius.*—A neat and pleasing little plant, which does not flower so frequently as several others, but is well worth growing on account of its symmetrical appearance. Introduced in 1835. A freely branching and pretty species, with a cylindrical stem 3 to 4 inches high; tubercles short and conical, quarter of an inch long, glaucous green, and furnished with a crown of yellow spines; flowers bright rose, with yellow anthers.

M. DOLICHOCENTRA, *Lemaire.*—A somewhat variable species of strong habit, especially abundant in the neighbourhood of Xalapa, and included in most large collections of Cacti. It was grown in the continental collections thirty years ago, but the date of its first appearance in England is uncertain. Several varieties have been described under the names of *phæacantha*, *straminea*, *Galeotti*, &c., but the last is generally considered synonymous with the first, and they are all chiefly confined to continental gardens. Stem

stout, 6 to 8 inches high, 3 inches in diameter; tubercles conical, narrow, half an inch long, crowned with small tuft of white down and a few white spines of irregular length; flowers of moderate size, pale rose or reddish crimson; fruits red.

M. FISSURATA, *Engelmann*.—This plant, so far as I can ascertain, is not in cultivation in England, and is named here chiefly to illustrate the *Anhalonium* section of the genus, of which it is a very good type. It is well described and figured by Engelmann, and presents a very different appearance to the *Mammillarias* generally, though not structurally distinct. The root is thick and turnip-like, the leaves being triangular in form, very thick, and with the upper surface strangely furrowed; they are arranged in a closely imbricated manner, very suggestive of some *Gasterias*, and from the centre arises the whitish pink flower about 1 inch in diameter and surrounded at the base by dense woolly substance. It is found in the same district as *M. pectinata*, chiefly on hard gravel or limestone soils.

The species of *Anhalonium* that are better known to cultivators are *A. elongatum*, *Salm.*, *A. prismaticum*, *Lemaire*, and *A. sulcatum*, all of which more or less resemble *M. fissurata* in the form of leaves and habit. They are curious species, and bear strange resemblance to other plants—for instance, the leaves of *A. elongatum* have been aptly compared to those of *Crassula perfoliata*, and of *A. prismaticum* and *A. sulcatum* to *Aloes*, especially *Aloe retusa*. These are all considered as *Mammillarias* now, Hooker and Bentham in this view following Engelmann and Miquel.

M. GRACILIS, *Pfeifer*, var. *PULCHELLA*.—Amongst the small-growing cylindrical-stemmed species of *Mammillaria* none surpass this in delicate beauty. It is indeed an exquisite little gem, most symmetrical in the arrangement of its spines, and is moreover very easily grown and readily increased, as the diminutive side branches or offsets are produced in great numbers. Very dwarf, 1 to 2 inches high; stem cylindrical, half an inch in diameter; tubercles small and green; spines in one series, white, spreading and closely set; flowers pale yellow, of good size, and attractive.

M. MICROMERIS, *Engelmann*.—Unique in form and very beautiful, readily distinguishable from all other species in cultivation, but resembling one described by some writers as *M. microthele*. It is a Mexican plant, and according to the author of the above name is found "from El Paso to the San Pedro river, also in a single locality east of this river, in naked places on mountain tops or sides, only on limestone, never in the porphyritic region." An exceedingly fine engraving of the plant is given in Engelmann's "Cactaceæ of the Boundary," and the distinguishing characters of a variety named *Greggi*, which is of rather larger growth, are also shown. In the species the stem resembles a flattened ball 2 inches in diameter and $1\frac{1}{2}$ inch high, having in the centre at the apex a circular tuft of wool-like down about 1 inch across, surrounded by a fringe of stiff white spines; tubercles very small and closely set, each bearing a diminutive star of radiating white hairs, which fall from the older tubercles, giving the lower portions of the plant a peculiar appearance. The flowers are very minute, with about five sepals and petals, pale rose-coloured, and succeeded by red berries one-third of an inch long.

M. MULTICEPS, *Salm.*—Chiefly remarkable for the much-divided character of the stem; the flowers are also of a pleasing shade of colour and produced rather freely. The lower divisions and branches of the stem can be removed and potted when it is desired to increase the plant. Stem dwarf, much-branched or divided, 1 inch high, half inch in diameter; tubercles one-eighth to a quarter of an inch long, narrow, conical, green; spines in two series, the outer white, very fine and numerous, the inner yellow, larger, and stronger; flowers pale yellow with a reddish line in the centre of the petals.

M. NEUMANNIANA, *Lemaire*.—A bold and distinct species, free in growth, and well worth a place in a small collection. Introduced from Mexico in 1845. Stem cylindrical, 5 to 6 inches high; tubercles stout, three-eighths of an inch long, dark green, with a tuft of wool-like material at the apex and a few tawny spines about half an inch long; flowers of a rosy hue.

M. OBIERIANA, *Lemaire*.—An attractive plant, especially when in flower, but at all times it is one of the neatest of the genus, its spines being very regularly arranged, and the contrast in colour between the inner and outer series is striking. Stem cylindrical, 3 to 4 inches high, 2 inches in diameter, very symmetrical; tubercles one-eighth of an inch long, dark green; spines in two series, the outer close and fine, the inner tawny, half an inch to three-quarters of an inch long. Flowers reddish violet.

M. PARKINSONII, *Ehrenberg*.—A very distinct species, of bold habit, and attaining a larger size under culture than the majority of the *Mammillarias*. It is found in several districts of Mexico, principally on calcareous rocks. It has been cultivated in England and on the Continent for some years, but the date of its introduction is uncertain. Stout-growing; stem 4 to 6 inches high, 2 to 3 inches in diameter; tubercles small, each bearing a star of diminutive white hairs, and four to five stiff erect white spines 1 to $1\frac{1}{2}$ inch long tipped with brown; flowers yellow.

M. PECTINATA, *Engelmann*.—Few of the *Mammillarias* equal this in beauty, and it is much to be regretted that the plant continues so scarce in English collections. It is an example of Dr. Engelmann's sub-genus *Coryphantha*, and is said to be found on the limestone hills of the Pecos, whence it was introduced to Europe about twenty or thirty years since. The flowers last a very short time, generally only about two hours in the middle of the day, but they are succeeded by fruits half an inch long, which remain attached to the plant for a considerable time. Stem conical or nearly globular, about 3 inches high and $2\frac{1}{2}$ inches in diameter; tubercles short and stout, each crowned with a rosette of white spines on one series, very even in size and regularly spreading half an inch or more across each star. Flowers yellow, generally produced singly from the apex of the plant and comparatively large, 2 inches in diameter, with very narrow and numerous petals, the sepals being also numerous, the outer reddish green and the inner resembling the petals. The woodcut (fig. 14) is an accurate reproduction of Engelmann's admirable engraving in the "Cactaceæ of the Boundary."

M. PUSILLA, *Decandolle*.—A diminutive but beautiful plant, meriting a place amongst the best forms of the genus. It is interesting, too, as being a native of the West Indies and South America, whence it was introduced in 1820. This species appears to be identical with those described by Harvey and others as *M. stellaris*, and is also probably the *M. stellata* of Loddige's "Botanical Cabinet." Dwarf; stem 1 to 2 inches high, cylindrical-globular; tubercles narrow conical, one-eighth to a quarter of an inch long, dark green; spines in two series, outer numerous, fine hair-like, white, inner fewer, erect,

and brownish. The flowers are freely produced, yellowish, the petals having a central line of rose.

M. RHODANTHA, *Link et Otto*.—The bright colour of the abundant flowers of this plant renders it a charming companion for the others named in this list, and will, moreover, bear a lower temperature than the majority; it has indeed been tried out of doors both here and in France during the summer months. It is a Mexican species, and was introduced in 1836. Several varieties are known and named, such as *neglecta*, *sulphurea*, *ruiceps*, *aureiceps*, and others, but they differ very slightly from the species. Stem 2 to 6 inches long, 2 inches in diameter, freely branching; tubercles conical, one-eighth to quarter of an inch long, having at the apex a tuft of white-down, rays of fine hairs, and six irregular white or yellowish spines quarter to half an inch long. Flowers produced in succession during the summer, bright rose, medium size.

M. SCHIEDEANA, *Ehrenberg*.—One of the prettiest and most distinct of the genus, and is of free growth and flowers profusely, also producing its reddish fruits occasionally, which have a pretty appearance nestling amongst the tubercles. It inhabits limestone districts at considerable elevations in Mexico, whence it was introduced to France in 1838, and to England some

Fig. 14.—*Mamillaria pectinata*.

years later. It should be in every collection. Stem cylindrical, globular 3 to 5 inches high, 2 inches in diameter; tubercles dark green, cylindrical, half an inch long, very narrow, quite distinct from the majority of species; spines yellowish, hair-like, and forming a small star nearly a quarter of an inch in diameter, much resembling the pappus on some of the *Compositæ*; flowers small and white.

M. PHYMATOTHELE, *Bergm.*—A strong-growing plant, which has been in cultivation in Europe for forty years or more, and is now found in most English collections. Its name signifies "tumour-nipple," and refers to the swollen tubercles. Several species of *Mammillaria* have the specific names terminating with "thele," bearing the same signification with a qualifying prefix, as *microthele*, small nipple; *macrothele*, large nipple; and *polythele*, many nipples. In others the Latin is substituted for the Greek, and we have *longimamma* and *magnimamma* with corresponding meanings. Stem 5 to 6 inches high, 2 inches in diameter; tubercles a quarter of an inch long, conical, dark green, crowned with a small tuft of white down, a few white, spreading, hair-like spines, and four to six erect yellowish-red central spines about half an inch long. Flowers bright rose.

M. RAPIDACANTHA, *Lemaire*.—The needle-spined nipple Cactus is an exceedingly pretty species, small in its proportions, but very symmetrical, and covered with the most delicate little rosettes of spines imaginable. They are indeed needle-like in form, brightness, and rigidity, and the clusters resemble crystals of ice. A plant sometimes seen under the name of *M. raphidacea* appears to be the same as this. Stem cylindrical, 3 to 5 inches high and 1 inch in diameter, slender and elegant; tubercles short, conical, a quarter of an inch long or less, dark green; spines in one series, spreading

star-like, eight or nine, closely set, a quarter of an inch long, white tipped with brown; flowers freely produced, about an inch in diameter, and purplish violet in colour.

M. SIMPLEX, *Haworth*.—This species is chiefly interesting in an historical point of view, for it was the first one introduced to Europe. It is mentioned by several of the old writers, and among them by Bradley in his curious work on "Succulent Plants" (1716). Ray states that it was grown by Bishop Compton at Fulham, and was also grown at Hampton Court in 1690. Linnæus described it under the name *Cactus Mammillaris*, and states with truth that it is covered with bearded papillæ like the *Mesembryanthemum*, has a milky juice like the *Euphorbias*, and the fructification of the *Cactus*, remarks which would apply to many other members of the genus. With *M. simplex*, *M. discolor*, and a supposed variety of the former named *prolifera*, which is now referred to *M. flavescent D.C.*, *Haworth* founded the genus *Mammillaria*, which has since been adopted by nearly all writers, though the number of species has increased a hundredfold since his time. It is a native of tropical America. Stem simple, globular, 4 to 6 inches high; tubercles conical, small, crowned with a white down and two series of spines, the outer about twelve, white, the inner four to six, strong and reddish in colour; flowers small, greenish white.

M. STELLA-AURATA, *Martius*.—"Golden Star" is a euphonious and appropriate name for one of the most attractive of the genus, and one that is a great favourite with all who are familiar with these plants. When in good condition the whole plant is covered with star-like rosettes of yellow spines, which impart a very distinct appearance to it, especially when in contrast with the white-spined forms. It is regarded as identical with *M. tenuis* of *Decandolle*. Introduced in 1835. Stem 2 inches high, half an inch in diameter, freely branched and dwarf; tubercles short and green; spines in a flat spreading star-like rosette, very numerous, one-eighth to one-quarter of an inch long, yellowish tipped with reddish brown. Flowers small and white.

M. WILDIANA, *Otto*.—A charming species introduced from Mexico to France in 1835; but it did not make its appearance in English gardens until some years later, and even now it is not very generally known. It is one of the most select, and should be included in the smallest collections. A crested variety has been obtained and deserves the notice of those who admire these abnormal forms. Generally very dwarf, 3 to 4 inches high, but occasionally taller and more cylindrical, closely surrounded by offsets which are freely produced. Tubercles conical, dull dark green; spines in two series, the outer very fine, white, and closely spreading, the others much fewer and larger, yellowish, and hooked at the apex; flowers rose-coloured, borne at different periods of the year and rather frequently.

The species named in this list include some of the best of those cultivated in England, the descriptions (except where otherwise stated) being taken from plants in the Kew collection, which have been examined and determined by the very careful botanist, Mr. N. E. Brown, of the Kew Herbarium.—*LEWIS CASTLE*.

(To be continued.)

PEACHES AT WILTON.

I AM much interested in the experiment in Peach culture at Wilton, described by Mr. Wright at page 27. It is a great satisfaction to hear of such a shrewd sensible man as Mr. Challis stepping out of the common rut, and his experiments themselves show that they are not of the haphazard description, but based upon reflection and intelligence. I purpose availing myself of the usual freemasonry privilege of the craft and calling at Wilton the first opportunity I have, and I shall be even more pleased to see Mr. Challis here at any time he may have the opportunity of calling. There are two or three points connected with his Peach trees I should be glad to have cleared up. They are trained, I understand, on "the extension system pure and simple," as Mr. Iggulden once described them, and as I gather from Mr. Wright's account now; and so far as it goes the system is found to answer, as I have no doubt it will anywhere. But the question which arises in my mind is this: Now that the Wilton trees have already filled the narrow cross trellises allotted to them (about 7 feet wide between the path and the front wall, and a little wider above the level of the doorway, according to the scale furnished in fig. 5, page 28), how does Mr. Challis propose extending them on the extension principle on which he began, or what Mr. Wright truly calls "the generous system of culture?" His trees have already reached the end of their tether, but the limbs cannot have nearly attained to their full or natural development on a trellis which only permits of a few feet of growth each way; and after this period, unless severe and frequent root-pruning is resorted to, the old plan of hewing back the limbs must be adopted—i.e., the restrictive system "pure and simple." The experiment is only in its infancy, and it was exactly such experience as he has yet to come through with his present trees that led me to give my trees so much room. I have at the present time one young Nectarine tree, five years old, that is exactly 26 feet wide to the extremities of the branches on a level line across the base of the tree about 1 foot from the ground; and on another older tree the branches on each side are about 18 feet and 20 feet long, and these have had to be shortened back and the trees root-pruned more than once to restrain over-luxuriance. What will Mr. Challis do with all this growth in the case of his trees when he has had them as long as I have had mine? I can see nothing for it but cutting off the whole of his annual growth that extends beyond the outer edge of his trellis already covered, and depending on back breaks to keep the trees furnished, and this will be restriction in its severest form.—*J. SIMPSON, Wortley, Sheffield.*

ORCHARDS AND PARAFFIN.—In reply to "T. W." (page 44) I wish to state that the mixture of colza oil and paraffin, to which a little soot and sulphur was added, as described on page 526 last volume, proved

quite effectual, and did no harm whatever to the trees to which it was applied. Peaches, Pears, and Plums were painted over young and old wood. If it is carefully mixed and used it will not do any harm. I put in the saving clause to prevent its being roughly made and applied. It is my practice to test everything carefully before using it extensively. I have this week tested it on different plants, and even on a spray of far-advanced Peach blooms, and see nothing wrong. I will forward a little as I mix it, carriage paid, to your correspondent for him to test and report thereon in your widely read Journal if he will send me his address through the Editor.—*A FOREMAN.*

SPECIAL SOCIETIES.

YOUR correspondents "Border Flower" and "X." do not really seem to write for information. Their object is apparent to the most obtuse understanding. I cannot tell "X." how to exhibit fourth and fifth-rate flowers so that they may obtain first prizes. If any correspondents will write to me I will gladly lay any propositions for improvement before the Committee, or if they can tell me of any schedules that are more liberally arranged for all classes of exhibitors I shall be glad. Further, everybody can exhibit and take prizes, whether they subscribe or not. I again repeat that the question of national utility need not be introduced. The subscribers are, I presume, satisfied—at least I hear no complaint. The societies can lay claim to the title of "National" as much as any society of the same kind ever could. I speak in the past tense, for the National Rose Society has decided to restrict the competition for its prizes to subscribers only; it must therefore drop the title of "National."

"Border Flower" seems able to give much more important information than I can. He publicly states at page 61 that one reason why growers encourage the shows is that they want to sell their seeds. Now I publicly request of him to give the names of growers who do this. I want to know the names of the growers who have seeds to sell. Personally I do not know a single grower who has an "eye to business" of the kind mentioned by "Border Flower." If dealers in such things did have an eye to business, what is there in it to find fault with?—*J. DOUGLAS.*

MR. DOUGLAS had no right to drag in the name of my late friend Mr. Woodhead into this controversy. I had too great a respect for him to have ever accused him of taking an unfair advantage. I had not the remotest idea of alluding to him, but to an exhibitor still living. Feeling that such a statement would give pain to both his friend Mr. Rudd and his worthy sister Miss Woodhead, I wrote privately immediately on receipt of the Journal to the former, contradicting Mr. Douglas's statement.—*D., Deal.*

SYRINGING.

WATER as employed in syringing acts in two ways; first, by inducing growth, and secondly in refreshing or cleansing. In the first case it prevents evaporation, and that means growth, for when a plant is not parting with its juices it is increasing, as the roots keep on absorbing, and it is this fulness that results in growth. Thus we syringe Vines, Peaches, and other fruit trees when they are being started into growth, and we also syringe plants that have rested and which we wish to start into growth. It is held, and no doubt justifiably, that this air moisture is of greater importance than moisture at the roots, especially in the case of plants that are known to not put forth roots in advance of or simultaneously with the growth. Syringing, or a moist atmosphere, is of more consequence in effecting a good break than water at the roots, simply because the moisture prevents evaporation, causes the filling of the sap vessels beyond repletion, and the buds burst. It is living on itself on the stored-up food or cambium, which only needs moisture with the needful heat to call it into activity.

Moisture tends to expand the contracted sap vessels and increases the flow of fluid, restoring the waste consequent on the resting process, for it must not be supposed because the plants are kept dry and cool that they are entirely inactive, as evaporation is going on more or less constantly. Those that have much young wood will be affected the sooner, as the evaporation is more powerful from young than old wood. Peach trees, for instance, kept dry at the roots will cast their buds, whilst the Vine is not affected, though kept very much drier than the Peach trees. We also syringe plants and maintain a moist atmosphere after repotting to check evaporation and thus keep the plant from suffering exhaustion; therefore we may conclude that whatever promotes evaporation checks growth, but the structure of the plant is thereby solidified and rendered healthful and fruitful. When growth is wanted, the more uniformly moist the atmosphere the more regular and constant will be the growth; but if we keep a plant constantly dripping with moisture it will not be long ere it becomes unhealthy, hence our best practitioners are averse to morning syringings in the cultivation of plants, preferring to damp the house well, and thus keep the atmosphere so charged with moisture as to prevent

undue evaporation, whilst at the same time the foliage is free to perform its functions during the best part of the day. This effected, the house is closed early and syringing or damping attended to, thereby producing a close moist sun-warmed atmosphere; then as night draws on the foliage becomes dry, the temperature is lowered, and the plants gradually rest. It is not good practice to syringe so late that the foliage will not become dry before night, and it is not advised to have plants dripping with moisture in the early part of the day, especially where it is not accompanied by ventilation.

Water is not always used in the best mode or of the right kind. Rain water is undoubtedly the only proper kind to use, and it should be clear. Excepting for the coccus or scale family it is the best insecticide. Forcible syringings will eject red spider, thrips, aphides, and mealy bug, and the neglect of its use is the real cause of plants being so much infested. Too many use the syringe as if it were a toy. Plants are treated to a downpour on the upper side of the leaves, doing no good, only keeping that part free of dust, whilst the insects are left to suck out the juices of the plant on the under surface. Were such a plant laid on its side and turned round so that every part could be thoroughly syringed the insects would be removed and the soil would not be soddened with water as is too frequently the case. Clear rain water will not injure anything, it will not leave any sediment on fruit, or stain the most delicate tint of foliage; but spring waters, from the mineral substances they contain, are not generally available for syringing, and should be used with care.—G. ABBEY.

ALPINE AND ROCKERY PLANTS.

In most English gardens a rockery has become a necessary consequence of the advance of outdoor gardening, together with the introduction of a greater variety of alpine and rock plants. Many of the rockeries, too, have been built by the owners, and a few I have had the pleasure of seeing are as regards exposure and situation faultless; but it is only in the summer that the disastrous effects of planting promiscuously anything that comes first to hand is seen. The graceful outline which in all cases ought to characterise a well-built rockery is entirely obliterated, and tall-growing plants in front disfigure what would otherwise be an agreeable feature. It may also be said to be the most favourable place where experiments may be tried in the acclimatising plants that are reputedly not hardy, or at least not generally seen growing outside in gardens in this country, and a few remarks on the principal rules to be observed in choosing situations both for these and the rarer alpine may be useful.

There are many circumstances which combine to preserve different plants through severe winters—such, for instance, as a congenial soil in which a sufficient amount of strength has been gained to enable them to withstand any keen weather; a proper position or exposure, the necessary degree of moisture, and many other things not generally taken into consideration by even the most attentive cultivators, but which nevertheless assist the plants through the most critical period. It is remarkable how few growers are aware of the necessity there is of using the greatest care and precision in either the making or choosing a position suitable to a certain plant, and will often place it where they think it will look best, and where, if it lives at all, will in all likelihood only eke out a miserable existence. It is not unusual to hear of many failures attending the attempts to establish newly imported plants; and the cause I have no doubt, in many cases at least, results from an injudicious choice of position—placing shade-loving plants fully exposed to the sun, *vice versa*, or, what is even worse, a bog plant in the driest position available. The above, of course, applies only to the more specialised or critical, because, on the other hand, cultivators who have had long experience in growing rock and alpine plants know something of the extraordinary tenacity of life which some of the stronger-growing varieties possess even in positions entirely the reverse of those with which they are associated in their natural habitations; so that even where nature is not studied the hardy constitution possessed by some of these renders the work of the cultivator not altogether uphill.

In the case of alpine proper, such as Saxifragas of the longifolia section, Androsaces, Dianthus, Sempervivums, and many others, it is always safest if possible to get them established in the chink or jointure between two rocks or large stones, provided that the necessary supply of soil has been well firmed in. This position will be found the most suitable for all plants that are injured by damp around their stems and that are of a trailing disposition, and even from an ornamental point of view when well established will be found far more satisfactory than

if plants in large flat unsightly pockets; besides, it utilises large portions of the rockery that would be otherwise bare.

Where large patches of Primulas, low-growing Potentillas, Campanulas, and Geums are desired, the best plan is to select pockets near the front well exposed, and raise the back by the addition of soil at least 6 to 9 inches higher than the front, placing plenty of small angular stones on the top, thereby retaining sufficient moisture. The tall-growing plants must be arranged nearest the top, and in all cases associated with the larger stones.—M. S.

DRESSING VINES.

HOT WATER VERSUS TAR.

MR. IGGULDEN, whose writings I read interestingly and, I hope, profitably, will not, I trust, think me disrespectful in not answering his letter on page 43 sooner. He will also, perhaps, excuse me for saying that when I read his last communication on the above subject I could not help thinking that, as the phrenologists say, he appears to have the bump of veneration largely developed. There are various objects of worship—some of them curious enough, as we all know—but the latest and not the least remarkable is the worship of tar. Truly fancy plays strange pranks occasionally. It was amusing to see dirty pigments denounced for smearing Vine rods, and then in the same letter to observe tar recommended as if it were the cleanest of materials; but to “almost worship it” indicates that the subject has a serious aspect. On this I will only say that while honest convictions deserve respect I am yet far from being a convert to tarolatry.

Your correspondent is perfectly correct in assuming that I have had experience with insects in vineries. There is perhaps scarcely one kind that I have not had something to do with—from the phylloxera on the roots to scale on the stems, thrips and mealy bug on the bunches, the curculio on the young shoots, and the tortrix on the ripening fruit. He is also perfectly justified in expecting me to make known my method of extirpating one of these insects—mealy bug. It is simplicity itself, and I think, though tastes differ, decidedly cleaner than tar. Tar is an old remedy, although it is made to appear as if new. The clay-and-tar pigment has been prescribed in the “Gardeners’ Year Book” for years past as a remedy for the American blight on Apple trees. For that purpose it is good, and it would be singular if it were not more or less efficacious in destroying a similar insect on Vines. It will destroy every insect that is painted with it; and so will hot water destroy as completely every one to which it is properly applied. The question is now reduced to one of hot water *versus* tar.

I am not quite sure whether I was pleased or disappointed when I observed hot water advised in the correspondence columns of the Journal last week as a remedy for the aphid on Auricula roots. As soon as I saw it I felt I was deprived of the credit of making, what Mr. Cannell calls in his advertisement, an “announcement;” but then I reflected on the counter-vailing advantage of having the efficacy of what I call my clean remedy in some measure confirmed by anticipation. This hot-water remedy, like the “new” tar doctrine, is really no novelty, it is just a good old method of destroying insects that has fallen into disuse; but though old, I do not remember its having been prominently advocated in your columns. It is, however, a safe, good, clean and cheap remedy for all that, as may be proved by anyone who will give it a fair trial in cleansing Vines from mealy bug and Roscs from aphides.

But to the Vine-cleansing. I commenced painting Vines with dirty pigments when I was ten years of age, and for ten more years consecutively I had a large share in this work; notwithstanding, we appeared to have also a large share of the insects we were supposed every year to destroy. For five succeeding years I had the pleasure of being relieved from the “dirty work.” The Vines were never painted, but washed with hot water, and we had no mealy bug. Eventually the longed-for time arrived when I became wholly responsible for the management of a garden, and in that garden was a vinery containing seven Vines, all equally well furnished with the pest alluded to. Here was an opportunity for experiment. After the Vines were pruned four of them were well daubed with clay, sulphur, soot, and lime, mixed to the consistency of paint with ammoniacal liquor from gasworks, which is as nearly like tar as Mr. Iggulden could wish, only perhaps a trifle cleaner. The other three alternate Vines were washed with hot soapy water, and the house was cleaned in the manner recommended by Mr. Murray on page 2. As much depends on cleaning the house and everything in it as the Vines. The insects pass the winter in the fissures of the under sides of

the woodwork of stages, in the dry crocks in flower pots, in the soil of Gloxinias and such-like plants that are wintered in the house, in bits of matting that some people leave enveloping the wires, and in the dry tendrils left in the same manner. But to the Vines. Those washed were quite as free from the pest the following year as those that were painted. There was, in truth, no insects left alive on the rods in either case; but a few found their way, as they usually do, from some obscure hiding place.

Mix, say, two ounces of soft soap, Grishurst compound, or nicotine soap in a gallon of water, and apply this to the Vine rods at a temperature of 160° exactly the same as a groom would apply it to the very dirty spokes of a carriage wheel. If any insects or eggs are left it will be the fault of the workman.

If your correspondent will try his clean system and my clean system on alternate Vines he will find the truth of what I have stated, and will not have much difficulty in determining which method is the most agreeable and expeditiously applied.—
IPSWICH.

ELECTION OF CARNATIONS AND PICOTEEES.

THE ELECTORS' RETURNS.

IN performance of the promise in my last letter (page 64) I send the selections as returned to me by those who have taken part in this election, as they will undoubtedly possess considerable interest to many growers.—
—G. RUDD.

From Mr. J. DOUGLAS, Great Gearies, Ilford, Essex.

CARNATIONS.

Scarlet Bizarres.

Admiral Curzon (Easom)
Fred Odwell
Arthur Medhurst (Dodwell)
George (Dodwell)
Mars (Hextall)
Robert Lord (Dodwell)

Crimson Bizarres.

E. S. Dodwell (Hewitt)
Harrison Weir (Dodwell)
Master Fred (Hewitt)
Rifleman (Wood)
Thomas Moore (Dodwell)
J. D. Hextall (Simonite)

Pink and Purple Bizarres.

Falconbridge (May)
Sarah Payne (Ward)
Mrs. Barlow (Dodwell)
William Skirving (Gorton)
Squire Llewelyn (Dodwell)
Squire Penson (Dodwell)

Purple Flakes.

James Douglas (Simonite)
Mayor of Nottingham (Taylor)
Earl of Stamford (Addis)
Squire Meynell (Brabbin)
Squire Whitbourn (Dodwell)
Miss Nightingale (Sealey)

Scarlet Flakes.

Clipper (Fletcher)
Sportsman (Hedderley)
Henry Cannell (Dodwell)
John Bayley (Dodwell)
Annihilator (Jackson)
Thomas Tones (Dodwell)

Rose Flakes.

DELPHINIUM NUDICAULE.

A CORRESPONDENT, on page 62, asks for information about this plant, and whether it is suitable for a summer bed. It is a plant I have grown regularly for several years, on rockeries and well-drained beds of made soil, where the climate is wet and the natural soil cold clay. Perhaps my remarks may not apply to the plant when grown in a dry climate and a warm soil. It is easily raised from seed under glass. If sown early and potted singly in May, the plants are fit to plant out by the end of June. This should be done without breaking the ball, as they transplant badly and are easily checked. They must also in all stages of growth, and at all seasons, be protected from slugs, where these vermin haunt, or they are sure to be found out and eaten down. The plants will flower the first year from August to the end of autumn. I have never tried lifting them to keep during winter, but believe that they will stand unharmed through any amount of cold they can experience in England. If they fail to appear the second spring the most likely cause of failure is slugs, which, when they have once found out the plant, are sure to stick to it till it is destroyed. Plants ought to be in flower by the end of May the second year, and if not allowed to get too dry they flower for three months. After this they seem to be done for. The plant is not by nature biennial, and if dug up after the second winter the rootstock, which is large and fleshy, seems sound, but in my experience it seldom breaks again, though protected from slugs by perforated zinc and soot. In this habit it resembles such plants as Platycodon and Adenophora, which form similar rootstocks, and in strong soils are equally shortlived. I should recommend your correspondent before he uses this as a bedding-out plant to try a clump of it—say a dozen plants—and see whether it is sufficiently trustworthy in his soil. I find it capricious, and while some plants do well others under the same conditions fail. It is clear from what I have said that those who wish to keep it should raise plants from seed every year. It ripens seed fairly well, unless the summer is unusually wet.—
C. WOLLEY DOD.

SPOT ON MASDEVALLIAS.

FOR some time past I have been considering and trying to gain information as to the cause of the black spot on the foliage of these plants which gives them any but a healthy or pleasing appearance. At first I was inclined to believe it was confined to the few plants I possessed and which had been purchased, but more plants were obtained from an entirely different source, and they were even worse than those previously procured. This disease was much more general than what I had really supposed, for I soon had opportunities of inspecting plants in various collections, and all had more or less a badly spotted appearance. I made many inquiries, but none of which resulted in information altogether satisfactory, and so I tried to find out if possible the real cause, thinking that by so doing it would be the first step in the right direction towards growing the plants with clean healthy foliage.

I believe that this disease, for it is nothing else, is brought about in the first instance by improper treatment. The main cause is cold, combined with a close stagnant atmosphere. Not unfrequently these plants are subject to a much lower temperature than Odontoglossums, and these are often to be found when grown in any number, in a house with a northern aspect. Even in this position during the summer shade may be dispensed with if the house is low, but this depends upon the surroundings of the structure. The atmosphere of a house in this respect is very liable to become saturated and stagnant. This is not so liable to be the case during the summer when air can be freely admitted as is the case during the autumn, winter, and spring. I do not believe in structures with a northern aspect for cool Orchids, although they like shade—that is, the direct rays of the sun screened from them; they like light, and every ray possible should be admitted to ripen and solidify their growth. The house in which the cool Orchids are grown at Drumlanrig has, I believe, a southern aspect, and is not heavily shaded, and probably there is not a sturdier healthier lot of plants to be found in Britain.

If cold and a stagnant atmosphere are the main causes, then warmth and a freely ventilated structure in which to grow these plants will effect a remedy. Such has certainly been the case with my young plants, for the foliage produced is now healthy and stout. The plants I possess are grown with the *Odontoglossums*, not at the coolest or yet at the warmest end of the house, but in the middle, and the minimum night temperature is 45° during the winter, and this only on very cold nights or during severe frost, often when the temperature stands 55° . The little heat given to maintain this temperature appears to suit the plants exactly, for spotless leaves are produced, and the plants increase rapidly. I have given my opinion, but my experience is somewhat limited, as I do not possess more than a dozen and a half of young plants. I shall be glad to see the opinion of others, for no subject is more worthy of discussion.—W. BARDNEY.

ABOUT CUT FLOWERS.

If gardeners were asked in what month they would least desire a demand for cut flowers and flowering plants, I think the majority would name January. Not that there is a difficulty in obtaining plenty of flowers in that month, but it is not easy to keep up a supply at this season. One of the very best of flowers is the *Chrysanthemum*, which is of great value in January, though I am inclined more and more to grow only white varieties for the time of year. Of equally easy culture are Zonal *Pelargoniums*, *Carnations*, *Lily of the Valley*, crimson *Van Thol Tulips*, *Hyacinths*, *Christmas Roses*, *Tea Roses*, *Camellias*, and *Eucharises*, which may form the main stay in the shape of flowers. Besides there are always a few *Orchids*, stove and greenhouse plants, and *Primulas* which may be usefully employed.

There are some general principles which should be borne in mind and acted upon at all times with regard to cutting flowers, and especially when there is a "run" at an untimely season. For instance, it is a mistake to cut flowers until they are fully developed, and in fact will not stand much longer on the plant. Thus only spikes of *Lily of the Valley* which are fully opened to the tip should be cut, in fact these last longer than half-opened spikes; or in the case of *Pelargoniums* only trusses which are opened to the last pip. *Roses* and *Eucharises*, or flowers which will not keep on the plant, are best cut, and kept stalk in water in a cool room. Even *Chrysanthemums* will keep for several weeks in a perfectly cool and dry room, when they would be useless if left on the plant. If this principle of employing only the oldest flowers is carried out the probability of a break in the supply is very much lessened, as there will be constantly younger flowers coming forward in all stages. As a rule I never cut any but these older flowers; to cut young ones is to use up the supply of a future day, which may need all that can be grown to meet its own requirements.

Another principle which may be emphasised is this—Study simplicity in arrangement. The more simple the arrangement of flowers the easier it is for a gardener to insure a supply. I do not make it a rule, but generally I do not mix different sorts of flowers together. It is also necessary to study the kind of glasses in selecting flowers to fill them. In large glasses or vases a cluster of small flowers is out of place, though on the other hand it does not always follow that only the smaller flowers should be used to fill small glasses. If it is desired to display a *Rhododendron* truss, an *Amaryllis* or a *Cattleya* to the best advantage, select a smallish glass which the individual will fill, and do not try to improve really fine flowers of that sort by employing other foliage. Even a spray of *Maidenhair* will detract from the beauty of such flowers.

Another point. Do not mix the finer flowers with commoner sorts. Keep *Eucharis* and white *Lapagerias* to associate with *Orchids*, and with these add only the finest Ferns—*Adiantum farleyense* or *A. seutum*, or the dark green *Asparagus plumosus*. With the commoner flowers it is not by any means an advantage to use Ferns alone for a setting. For large vases, foliage of *Rex Begonias*, *Callas*, *Hollyhocks*, *Ivy Pelargoniums*, &c., are all extremely useful and suitable. Leafage is in its way just as much admired as flowers, and there is no reason why gardeners should confine themselves to a few Ferns. As a rule, let every flower stand clear of its neighbour. We may make an exception to this rule, and show a glowing bunch of *Pelargoniums* on a setting of their own foliage, but generally lightness is to be commended. Speaking of the latter reminds me that it is bad taste to mix dark-coloured varieties and those of a rosy shade together. Keep the latter to mix with light forms like *Aida* or other flowers. These help to show off the beauty of each other, but if mixed with the crimson kinds the effect of both is spoiled.

Much that has been written about vase-furnishing applies with equal force to table decorations. There are three simple modes of decoration which may either be separately employed or conjointly. For small tables cut flowers are most suitable, and these may be either arranged in small glasses or laid on the cloth. Tables to dine say from eight to a dozen and upwards are generally decorated with

plants as well as flowers. The simplest way of using plants is to stand them in vessels of plate or some kind of earthenware, or to stand them on the table amid a bank of foliage and flowers. In the latter case the fewer flowers employed the better. Nothing surpasses the common *Selaginella Kraussiana* as a groundwork, and if it is healthy and well grown no Ferns will be required. As a rule half a dozen large blossoms round this will be sufficient. White, pink, or crimson flowers are most suitable. *Chrysanthemums*, *Eucharises*, *Pelargoniums*, and *Camellias* are very suitable for the purpose, but they must be good. Small plants are sometimes placed round the table, crimson *Tulips* or three sprays of *Lily of the Valley*, or three plants of *Rivinia humilis* are well adapted for this purpose. These require no flowers amongst the moss. If foliage plants are used, then three *Carnations* round each, or as many *Bouvardias* or double *Primulas* do well. I much prefer to have all the plants alike. Small glasses filled with flowers are very pretty. Flat glasses should be filled with single trusses of *Pelargoniums* backed with a leaf of the same, or a *Chrysanthemum*, *Camellia*, or *Eucharis*. Tall narrow glasses are suitably filled with *Lily of the Valley*, small *Pelargonium* trusses, *Bouvardias*, and *Dendrobiums*.

In placing flowers on the cloth it is necessary to avoid light-coloured flowers unless some dark material is placed for the flowers to rest on. But this I do not like, it is artificial. Nothing is so homely as a white linen cloth, and it is easy enough to select colours to show on that. The main point to bear in mind in this form of decoration is to employ good flowers, and, as a rule, large ones are to be preferred. As far as possible use the foliage belonging to the plant, and when using Ferns select the *Adiantums*, such as *A. tenerum* or *A. farleyense* in preference to the common *Maidenhair*, which is too small in the pinnæ to show well. As with the plants, I like to employ only one, or at most two kinds of flower. These are laid on the cloth just before dinner time, and removed immediately dinner is over, so that the flowers receive no damage.

We have some pretty earthenware pots or small vases for decorating the breakfast table. These hold a small Fern out of a thumb pot, or a single *Tulip*, or two or three sprays of *Lily of the Valley*, and look very pretty and refreshing. I find the latter and *Tulips* do very well without any soil, merely keeping the roots in water, which is hidden by a tuft of *Selaginella*.—R. P. BROTHERSTON.

PEACH TREES CASTING THEIR BUDS.

LAST season our Peach trees in the earliest house cast the principal part of their flower buds, and we attributed it to dressing them with Gishurst compound, although the solution was not so strong as advised on the cover of the box. A Nectarine tree in the same house was dressed with the same solution with a different result—few of its buds fell. Neither of the trees lost any of their wood buds. The trees were all badly infested with brown scale, and received two dressings with the solution. It had the desired effect with the scale, so that there was scarcely a trace of it this season. After pruning the trees this season they received a washing with equal quantities of tobacco juice and water, and have cast very few buds. Spring water is used both for syringing and watering the border. It is warmed to the required temperature.—L. T.

I do not think that giving the trees spring water is the cause of "Alpha's" trees casting their buds, as my trees have done precisely the same as his, and mine have been watered only with rain water. We must look for something else; but what I am not clever enough to make out, but perhaps some of your readers can.—A. S. D.

LILIUMS FOR MIXED FLOWER BORDERS.

IN a note on this subject on page 37 Mr. Sanders speaks of me as having discovered the secret of the successful open-air cultivation of *Lilium auratum*. Though I cannot claim to have done this, I have cultivated so many different *Liliums* for several years in the open air that a few notes for the sake of comparison may be of use to some readers. As for *Lilium auratum*, we have had elaborate theories propounded in different gardening journals to explain the reason why imported bulbs generally flower once tolerably well and then die. No doubt in *Liliums* as in nearly all bulbs, the new bulb which forms whilst one year's growth and flowering are going on, gathers a store in preparation for the same process the next year; but the great constitutional disturbance caused by what the imported bulb has had to undergo, though it does not destroy the flowering power already collected under the suns of Japan, causes the bulb to exhaust itself in the effort without making another bulb. If these imported bulbs are examined as soon as their flowering is over it will generally be found that no roots have been made beneath the bulb, but only from the crown of it, and that the bulb is dwindled and unhealthy and incapable of flowering or even growing the next year. A few out of every hundred do better, and the more

favourable to healthy growth the conditions have been to them during their first year in their new home the larger the proportion that will succeed. No one should consider that he has failed with *L. auratum* unless he has tried sound healthy bulbs raised in England from English seed, or at least bulbs which have been grown in England after three or four years' naturalisation. I cannot think that borders in which *L. lancifolium* (*speciosum*), *L. Thunbergianum*, and *L. tigrinum*—all of them more difficult to please in the matter of soil than *L. auratum* is—will not grow this latter kind well. The only suggestion I can make is that the soil may be too sandy, as *L. auratum* requires more moisture to do well than the others mentioned.

I observe that *L. bulbiferum* is included in Mr. Sanders' list. I have never yet succeeded in getting a bulb of the true *L. bulbiferum*, a Lily bearing little bulbils in the axils of the leaves all up the stalks. I think the Lilies generally called *bulbiferum* are either *L. croceum* or some hybrid of it; but by whatever name they are called, some of these hybrids are amongst the handsomest ornaments of our mixed borders in the month of July, being admirably suited to the English climate. In some catalogues they are called hybrids of *L. davuricum*, in others *L. umbellatum*; but there are many differences of height, habit, and colour, and nearly all are good.

Two or three Lilies which do very well in my mixed beds thrive in a soil too stiff and retentive to grow either *L. elegans* (*Thunbergianum*) or *L. tigrinum*, but they do not refuse to thrive in a lighter soil. They are *L. Szovitzianum* (*colchicum*) and the varieties of the common *L. Martagon*, white, purple, and very dark. The first-mentioned, known also as *L. monadelphum*, is a very handsome border flower, growing when established 5 feet high or more, and making heads of from six to twelve citron-yellow large spotted flowers about the end of June. *L. testaceum* (*excelsum*) does well in the same soil, but is less handsome.

Then there are two scarlet Martagons, *L. chalcedonicum* and *L. pomponium*, both very striking Lilies, and doing well in soil neither too dry nor too retentive. Care should be taken by arrangement with dealers to get these Lilies directly they are out of the soil, and favour should be made with the sellers not to cut off the roots. The state in which Lily bulbs generally come into the market makes it wonderful that they ever live at all, not that they take at least two years to recover themselves. I have said nothing about *L. pardalinum*, which, with the damp subsoil it has in my garden, I have never found to fail in any part. It is not one of the handsomest of Lilies, but ought soon to be one of the cheapest. *L. Washingtonianum* rarely does well in the open border in England, and *L. superbum* must have a damp soil. I think the latter at best an over-rated Lily, as it is always deficient in brightness of colour. *L. canadense rubrum* is a real gem amongst Lilies, and will do wherever *L. longifolium* does well. Next to it in merit in the same species comes *L. canadense flavum*. The mixed colours of the species are neat and elegant; still all the *L. canadense* are somewhat capricious about soils. *L. Humboldti* is a fine Lily, but cannot be trusted to do well, and being still expensive should be tried sparingly.

L. giganteum is more to be depended on in sheltered borders, and the many hundreds of thousands of home-grown seedlings which must now be approaching flowering size ought soon to bring this Lily within the reach of every garden.

I think I have now mentioned most of the leading Lilies suited for outdoor cultivation in England. Of all the established Lilies I have tried I have found *L. candidum* and *L. tigrinum* in all its forms the least accommodating and the most difficult to please.—C. WOLLEY DOD.

EUCHARIS AMAZONICA.

THIS beautiful stove plant is without doubt the finest of the *Amaryllis* tribe. The treatment under which I have grown it and been fairly successful is as follows:—

When an old pot has become too full of bulbs I shake them out, and divide them carefully with as little injury to the roots as possible; after division they are washed free from all decayed roots and old soil. The bulbs are then sorted into sizes, placing the largest, eight or ten in number, in a pot 10 inches across, then following with about sixteen of the next size, the smaller being placed in pans to be grown to flowering size.

The compost used in potting consists of one-half loam, one-fourth horse droppings from an old Mushroom bed well reduced, and one-fourth sand, with a good dash of charcoal dust and bone dust all being thoroughly incorporated. The pots are well drained with a little rough turf on the crocks. After potting the plants are shaded until fairly established, they are then brought into more light; at the same time always avoid bright sunshine, as the foliage is very easily injured by a sudden glare of light. Discretion is used in watering at all times, parti-

cularly so after the plants are newly potted; for if the soil becomes sodden the roots very soon go off, and it then requires great care to start the plants. After once fairly starting weak liquid manure is given about twice a week, a handful of soot is also occasionally supplied.

By having bulbs of different sizes constantly growing a succession of flowers is at command all through the year. If a little bottom heat is at command so much the better, but by careful and judicious treatment after potting equally good results can be obtained without it. The plants are grown at all times in a stove, the temperature of which is rarely more than 80°, or less than 60°.

Another mode of culture where bottom heat is at command, and which answers exceedingly well, is to plant the bulbs out in a bed, using the same kind of soil for them as for potting. When once well established they do not need disturbing for years. Of the two ways of growing them I prefer the latter, as flowers of a finer quality and in greater numbers from a less amount of space are obtained.

Eucharis amazonica is subject to one or two pests, the worst of which is mealy bug, sponging with soft soap and warm water being one of the simplest and best remedies. There is a smaller-flowering *Eucharis*—i.e., *E. candida*, which grows equally well and flowers quite as freely. The flowers for cutting have very few equals, and the plant deserves all the care and attention that can be bestowed upon it, and for market purposes it cannot be excelled.—WILLIAM JACKSON, *Benton Park, Randon.*

[The third prize paper read at the Leeds Gardeners' Meeting.]

HOLLYHOCKS.

WHAT is there in the floral world that can take the place of these noble flowers? In my opinion there is nothing so striking and unique in appearance as they are. I am not an old man, but I remember at least twenty years since what a grand lot of them with a great variety of colour and very large double flowers my grandmother had in the old country garden where I first learnt to love hardy flowers. Some of the stools were many years old, but the stock was constantly renewed from seed selected with a discriminating eye. There were large clumps, between similar ones of *Delphiniums* and *Monkshoods*, and they towered up 7 and 8 feet high. Last January I visited the dear old spot and found Hollyhocks still a favourite flower, and from what I could gather they had, or did not suffer, from the disease which has caused so much vexation to many. Of course it was difficult to ascertain the exact truth respecting such an invader from those wholly unacquainted with the nature of such parasites, but certainly what growth could be seen evidently bore no traces whatever of the fungus, and I intend to have leaves sent me at different times during the ensuing season, so as to feel quite satisfied that the plants in that part of the country are not infected; for I have no doubt there are many quiet country gardens where the Hollyhock has been grown for decades in which the *Puccinia* is unknown. I always keep my plants in two or three places, so as to avoid, if possible, all of them becoming attacked. In one batch three weeks since I noticed it making progress, but could not detect the least sign of it on the others. The infested plants were taken in hand at once, all the leaves were removed, and about an inch of the soil scraped out of the pots, and the whole pot plunged in a strong solution of soft soap, with about double the quantity of Fir tree oil prescribed for a given quantity of water; the dipping was repeated for four days, and although the solution was strong enough to injure the plants to some extent, yet they are growing freely again, and I do not observe any of the disease and hope it is destroyed, but am not at all sanguine on this point. Last year I had two batches of plants from different growers, one in Scotland, the other in Newcastle, and both senders represented the plants as quite clean and perfectly free from the fungus; but upon unpacking them I noticed the well-known spot, and although I dealt severely with them, I could not stamp it out, so had to destroy them.

I think it much better to grow a fresh batch from seed every year, securing the seed from a reliable source to start with, and afterwards saving over from the best flowers, for as a rule they seed pretty freely. If seed is sown thinly in pans at once and placed in gentle heat—say the greenhouse—there will be ample time to get flowers from them in the autumn; at least, many, if not the greater portion of them will flower, and the rest next spring, but no time should be lost now, and it is important to sow them thinly, so that they will not require disturbing before being planted out, which they may be after being hardened off in a cold frame. Encourage them to grow as freely as possible, and have the ground deeply dug or trenched in which they are to be planted and heavily manured, for they are great feeders. A large space of ground need not be occupied with them the first year, as they may be planted thickly until they have flowered, when it can be judged whether they are worth keeping or not, after which they can be planted as isolated specimens or otherwise, and enjoy more scope for their development. Delphi-

nium seed sown now and treated in the same way will produce flowering plants by the autumn.

Those who possess named varieties of Hollyhocks should place the stools now in a little peat, or if they are in the ground cover them with a handlight. If placed in heat, of course they will come on quicker, and consequently produce better plants the first season. When the cuttings are fully active, take them off with a heel, if intended for striking, and insert them in small pots of light sandy soil and place in the propagating pit, when they should be carefully watered—not kept too wet—and in about a fortnight they will root. They can also be grafted upon pieces of roots, selecting those about the same thickness as the shoots. This plan is generally adopted where they are largely grown. Ordinary side grafting is the simplest and best way to manage them, and when done place them in small pots of sandy soil and plunge in heat, and in due course, other things being equal, they will unite and form good plants; and like Roses, if planted below the union, will quickly be upon their own roots. I usually select seedlings for grafting, as they are more vigorous than portions of roots taken from other plants, and if they are grown in small pots for the purpose, the ball can be turned out, sufficient soil removed to put the scion on, and the whole returned again to the pot and then placed in heat. This is a very simple and generally successful way of increasing them. Supposing they are not now propagated at all, there will still be a good chance to increase the stock in July by eyes selected from the lateral shoots, which are generally freely produced. Examine the buds in the axils of the leaves, and many of them will be found to be leaf buds. These should be cut up similar to Vine eyes, leaving about an inch of stem each side of the eye, and pot them separately in small pots, leaving the bud slightly above the soil, and plunge in a brisk bottom heat, either in a hotbed or in the propagating bed inside, and in due course the bud will expand and roots will be emitted from the under surface, and before winter sets in really good plants may be had by this means. All the buds will not grow, but with care a good percentage of them will turn out most satisfactorily. I struck a good batch during the last two seasons, and a few days since I repotted those which were worked last July upon their showing signs of activity. They were in 3-inch pots, and are now shifted into 5-inch size and placed in a cold frame, there to remain till the end of March or early in April, according to the weather, when they will be planted out in well-prepared ground, which to insure success is a very important item; indeed it is absolutely necessary, especially if the soil is stiff, to thoroughly work it, if they are to make the best of the season.—T.

REVIEW OF BOOK.

The English Flower Garden. By W. ROBINSON. London: John Murray, Albemarle Street.

FLOWER gardening has made considerable advances within the past quarter of a century; a greater diversity of styles has come into favour, and there has been a gradual awakening to the fact that it was a mistake to rely exclusively upon the so-called standard bedding plants, such as Pelargoniums, Calceolarias, and Lobelias. The brilliant effect produced by tastefully arranged beds of these is admirably adapted for some positions when employed in moderation, but advocates of this style of bedding have done their cause injury by excess of zeal, and there is no doubt but that this has in a great measure contributed to a steady revolution in taste. A decided step towards relieving the sameness produced by a repetition of brightly coloured flowering plants was the introduction of the carpet style of bedding, in which the plants, consisting of those distinguished by different coloured foliage, possessed softer and quieter tints, and produced in combination more pleasing harmonies of colour than could be expected from the others. Though this has been as unmercifully ridiculed as the Pelargonium style, its merits are well established and its popularity unquestionable. A third style is that in which hardy plants are chiefly employed, and this also has been much advanced and developed in recent years. It is a pleasing revival of an old taste, for the border of hardy plants and florists' flowers formed the chief feature in gardens long before the more tender exotic plants were largely employed in outdoor garden decoration. In few establishments, however, were any elaborate attempts made in the arrangement, and it is in this respect principally that the advance is noticeable. Spring bedding is only a form of this, and the beautiful effects produced by tasteful displays in this method are now familiar to the public, and its value is fully recognised. Yet taking the borders or beds of hardy plants alone, it is surprising how great an amount of pleasure they will yield during a great portion of the year when stocked with a judicious selection of the most attractive species and varieties. That the popular knowledge of such plants is limited to a small proportion of the total number known and procurable is undeniable; it is equally clear that an extension of such knowledge is very desirable and likely to add much to the beauty and interest of gardens generally. The object of the work now before us is to assist in this object, and both in design and execution it is admirably adapted for purpose, as it is a reliable compendium of the best information

obtainable upon the subject, and to which many of the most experienced lovers of hardy flowers have contributed.

The subject is treated in two parts. The first, to which 124 pages are devoted, deals with the style, position, arrangement, and the practical matters connected with the formation of flower gardens. It is accompanied by a number of excellent engravings of garden scenery to illustrate the principal effects obtainable by appropriate planting in the neighbourhood of mansions, a few designs of carpet beds, and figures of subtropical plants. The second part, which forms the bulk of the book, containing over 300 pages, is devoted to the description and culture of the flowers suitable for culture in the open air. This, like the preceding, is thoroughly well done, being the work of a number of specialists whose services the editor freely acknowledges, specially mentioning those of Mr. W. Goldring. The genera are arranged alphabetically, treated very fully, and profusely illustrated. Taking the Campanulas for instance, no less than thirty-three species are represented; and other large genera, such as Clematis, Lilium, Narcissus, and Primula, are similarly well described and figured.

As regards type, paper, binding, and general finish this work is all that could be desired, and altogether it is the best on the subject that has yet been produced.

KITCHEN GARDEN.

The Weather.—Plenty of rain and a generally unusual mildness have been the leading features in the winter so far, and nothing could be more favourable to the growth and preservation of vegetables, as well as for tilling the soil. Market gardeners would probably be glad to see many vegetables scarcer, but buyers will not be of this opinion; and many private growers will have much to be thankful for, as in many cases winter supplies tax their resources to the utmost, and a severe November or December give much extra work in forcing to keep up supplies in spring. This should not be the case this spring, as Broccoli are turning in profusely. Spinach is large and succulent in the leaf, and other things remain fully developed. Should frost occur, however, as it no doubt will, the condition of matters will soon change, and cultivators should do their utmost to be prepared for this. Forcing has been simple work so far, and ground work, such as digging and trenching, should not now be behind in any case. A mild January often tempts beginners to sow freely, and by the end of March the mistake is too often apparent, but it will be well if those who are guided by the weather will confine their operations to thoroughly prepared soil, sheltered corners, and limited sowings.

Winter and Spring Cabbages.—These are healthy and green, and a general earthing-up should now be given. Where the soil is mellow this may be easily done with a drag hoe, but where retentive a fork should be used. The soil should be drawn well up to the collars of the plants, as this will give them needful support when the heads are heavy. It also prevents the wind shaking them, and in case of frost would afford them much protection. The small plants which are left in the autumn-sown beds are now large and ready for going out, and a piece may be planted with them at any time. The soil for their reception must be well manured. A little seed of an approved early variety should be sown in some warm corner, and this will give a very good succession to the others.

Onions.—Manure ground heavily for the reception of those plants raised from seed sown in the autumn. Sow seed of one of the early quick-growing sorts to give a supply of young plants for drawing when the autumn Onions are too large and before the spring plants are fairly in.

Round Spinach.—A few rows of this may be sown. A light dry soil suits it best at this season, and as it will not be very long on the ground special preparations need not be made for it. We generally sow our first crops of this between the rows of Peas put in during autumn, which are not staked, and we have many good early pickings from plants grown between the Strawberry rows on a south border.

Hotbeds.—These should be made up in succession for the reception of early Potatoes, Carrots, &c., and where materials of the kind are plentiful, many young Cauliflower plants, Lettuces, and Radishes may now be sown in frames, or between the rows of Potatoes where the latter are planted wide enough apart.

Globe Artichokes.—These are greener than we ever saw them at this time, and if severe weather comes the consequence may be serious, as they will not bear much frost. No attempt must be made yet to clear the litter from around them, as this will benefit them until the end of March.

Mint.—Where this is wanted green with early lamb a quantity of roots should be taken up and placed in pots or boxes, then plunged in a gentle heat.

Broccoli.—Many of these are hearting now. Backhouse's is our best, then comes Osborn's and Snow's. Where more heads are ready than is wanted cut and store them in a cool place. All the leaves should be trimmed off, and the short piece of stem attached to each head should be

pushed into damp sand or leaf soil; in this way they may be preserved for a month at least.

Frame Potatoes.—In notes respecting these (page 52) Sharpe's "Victoria" should read "Victor."

FRUIT-FORCING.

PEACHES AND NECTARINES.—*Earliest House.*—Attention must still be given daily to the late-blooming varieties, passing the camel's-hair brush lightly over the flowers on fine days. This operation takes up some little time, but it is one for which we are amply repaid in the feeling that no detail has been neglected which was likely to lead to success. When all the fruit is well set, syringe the trees daily in fine weather with tepid soft water, which will soon remove the remains of the blossoms and be a means of keeping insects in check. If, however, the young growths should be infested with aphides, fumigate upon a calm evening moderately, as the tender foliage is very susceptible of injury by tobacco smoke, especially if it be in the least wet, therefore have the foliage dry and fumigate moderately on two or three consecutive evenings. Disbudding must be proceeded with cautiously, so as to avoid giving a check to the roots. Commence at the extreme tier of the trees and work towards the base, removing the foreright shoots only in the first instance. Where there is a thick set of fruits, a few of those on the under side or at the back of the trellis may be removed, as the crop must be selected from those fruits which occupy the upper sides of the shoots; and in thinning the smallest and least promising only must be removed, as the thinning of the fruit needs to be done very gradually, especially at this early season. The night temperature should be kept at 55°, and on mild nights 3° to 5° warmer, with an advance by day of 10° to 15° from sun heat. Be careful in admitting air, guarding against exposing the young growths to cutting draughts in clear frosty weather. A few degrees' excess of sun heat will not do any harm, and is better than admitting cold air to keep the temperature down. Examine inside borders, and give the roots a good watering with weak liquid manure, which must be given in a tepid state. Avoid manure in a gross condition for mulching, it only encourages gross growth, and is positively injurious.

Second House.—The trees started at the commencement of the year are in full bloom and promise well. Where the trees can be depended on as good setters and the bloom is abundant draw the finger down the under sides of the shoots, thereby removing all the pendent blooms, which ought to be done before the flowers expand. Artificial impregnation must be resorted to, or a hive of bees will do it much better. If any of the large-flowering varieties, as Grosse Mignonne and Noblesse, are deficient of pollen, collect that of the smaller-flowered sorts, as Royal George, and apply it to the stigmas of those deficient of pollen. Syringing will have ceased, as it ought during the flowering season, but maintain a genial condition of the atmosphere by sprinkling the paths in the morning and afternoon of fine days. If there be any deficiency of moisture in the borders give a thorough soaking with tepid water. Maintain the night temperature at 50°, falling a few degrees on cold nights, 55° by day by artificial means, and 60° to 65° from sun heat, ventilating on all favourable occasions.

Houses to Ripen Fruit in July.—Where there are several houses and it is desirable to have a succession of fruit, a third house may now be started; indeed they have started, the buds being on the move and swelling fast, unquestionably due to the unusual mildness of the season. The ordinary midseason varieties now started will ripen in July. The house, no doubt, has been cleansed, the trees pruned, dressed, and secured to the trellis. Give the inside border a thorough watering, employing weak liquid manure in a tepid state if the trees are aged, but young trees will hardly need any stimulant. If there be any dryness at the roots it will be necessary to bring the soil into a thoroughly moist condition by repeated waterings. Syringe the trees twice a day, morning and afternoon, the latter sufficiently early to allow the trees to become dry before night. Turn on the heat in the morning to raise and maintain a temperature of 50° through the day, ventilating freely above that degree, and maintain a night temperature of 40° to 45°.

Cherry House.—Cherry houses are not so frequently seen as they should be. The house must be light, well ventilated, and have moveable roof lights. A lean-to answers well, having a trellis about 15 inches from the glass, and the trees planted in front, or a half-moon trellis in front will admit of trees being trained on the back wall. The borders should be entirely inside, and should be about 6 feet wide. Wide borders are quite unnecessary, in fact they are injurious. The borders must be well drained, a 3-inch drain pipe being taken up each border, and over this a foot to 15 inches of rubble for drainage, and to keep this porous a layer of turf grass side downwards, and then 30 inches depth of soil—good fibrous loam, with a tenth of old mortar rubbish incorporated. Grit is also essential; if deficient of this, add road scrapings equal to a sixth of the whole, thoroughly mixing and putting together firmly. The best sorts for forcing are Circassian and May Duke of the dark-coloured, and of lights Elton and Governor Wood. If trees can be procured that have been trained to walls for four or five years, they should be selected as they come into bearing at once. Now is a good time to plant the trees, indeed February is the best month for introducing fresh trees into houses at work as well as for planting new ones.

PLANT HOUSES.

Nepenthes.—These are amongst the most ornamental and interesting plants that can be grown in the stove. They will do well grown either in pots on the stages or in baskets suspended from the roof; the latter is

preferable, because the side stages can be occupied with other plants, and when hanging from the roof they show themselves to the greatest advantage and possess a very pleasing appearance. Plants requiring baskets of a larger size should have them without delay; place at the base of the baskets a layer of large crocks, which should be covered with sphagnum moss, and then the remaining portions between the ball and the sides of the baskets filled with peat fibre and sphagnum moss in equal proportions, to which may be added a few small crocks or charcoal. Remove as much of the decomposed material as possible, but care must be exercised not to injure the roots, for they are easily broken. If the plants have been cut down and the lower portion of the stem is bare, peg it upon the surface of the soil and cover it with moss, and in a short time it will emit roots freely, especially if half cut through where the growths start away; by this means the plant will in a few months be independent of its former roots. These plants should not be allowed to grow tall, and thus become shy of producing pitchers; on the contrary, as soon as they fail to form them freely cut them down close to the base, leaving two or three eyes, which are ample. If cut down at once the plants will soon commence growth, and before autumn will have made good plants, producing pitchers freely.

Propagation.—After cutting a plant down the stock is readily increased by cuttings made from the stem. The stem should be cut into lengths possessing two joints each. In making the cuttings the cut near the lower joint should be clean, but neither of the leaves should be removed. These should be inserted in 3-inch pots filled with sphagnum moss and a little coarse sand, the top eye only being left out of the moss, while the leaves should be supported with small stakes. After this a good watering of tepid water must be given, and the pots plunged in brisk bottom heat under handlights, bellglasses, or a close frame, where they should remain without being disturbed until they are rooted. If shaded from strong sun and the foliage dewed with the syringe occasionally, nearly every one will be found to root and produce a young shoot from the top eye. After they are rooted some care and attention must be devoted to hardening them, for they are a long time before they are sufficiently hardened for placing in baskets and suspending. After the young plants are sufficiently hardened to be placed in baskets the old foliage may be removed and the plants mossed up to the place where the young shoot starts away. By autumn fine plants will be produced, which will commence to form pitchers freely.

Alocasias.—The foliage of these plants is very ornamental in the stove, and wherever such are appreciated they should be grown. They may without further delay receive their annual potting. Turn out the plants and remove from them the whole of the old decomposed compost, as they dislike soil in a sour or saturated condition about their roots. If the stems of these plants have become long remove the lower portion, which will allow them to be dropped lower in their pots, and impart fresh vigour to the plants afterwards. The pots for these plants should be half-filled with drainage, and the plants when potting is finished well elevated above the rim of their pots, similar to Orchids. The compost should consist of equal parts fibry peat and sphagnum moss, with lumps of charcoal freely intermixed. The top may be surfaced with a layer of sphagnum moss, but ample room should be left for a good top-dressing during the summer when the plants are in active growth. A little cow manure in a dried state applied to the surface I have found very beneficial to them. If practicable after potting, give the plants bottom heat until their roots commence working, when they can again be removed to their position in the stove. The portions of stem may be cut into lengths if it is desirable to increase the stock. If about 1 inch long and placed in light sandy soil in pans, every portion will produce a plant which can be grown on together or singly, as thought most desirable.

Anthuriums.—All fine-foliage varieties of these that occupy the stove may also be subject to the operation of potting. The whole of the old compost should be removed with as little injury to the roots as possible. Give a good quantity of drainage, for these plants delight in rooting near the surface, and when in active growth require abundance of water. The lower portion of the stem generally rises in the space of twelve months well above the surface of the compost, and roots are freely produced. In potting place them as low as practicable, and as they grow a surface dressing may be given them with advantage. Elevate above the rim of the pots the same as the Alocasias, and use the same compost.

The useful and beautiful *A. Schertzerianum* that has been up to the present time in a temperature of 55° may now be brought into the stove, and in a very short time they will produce their bright scarlet spathes. These may also be potted as soon as they show signs of root-action, which will not be long after they are removed into the heat and moisture of the stove. The old compost should also be removed from these; in fact, when potting is needed carry out the directions given for the fine-foliage varieties, and use the same compost.

THE BEE-KEEPER.

NOTES ON BEES—PRACTICAL MANAGEMENT.

Preventing Swarming—Utilising Swarms, &c.—It is very important to the bee-keeper to know what he can do to prevent his bees from swarming at a time when he does not wish

to increase the number of his stocks, but rather to obtain as large an amount of surplus honey as possible. To attain this desirable end many praiseworthy efforts have been made, and eminent apiarians have devoted much time and attention to it. The result, so far as my own experience goes, is that though much can be done to lessen the chances of swarming, no plan which has yet been made public can be relied upon in all seasons and under all the various conditions in which we find our bees at the time.

Atmospheric influences have much to do with it, and it not unfrequently happens that the excitement caused by giving additional supers or removing sections will start a swarm off. To talk about overhauling hives at regular intervals and removing queen cells so as to prevent swarming, is altogether out of the question; no experienced bee-keeper would entertain the idea for a moment, on account of the trouble and worry involved. Confining queens to a particular part of the hive sounds well in theory, but in practice it does not as a rule succeed; so that after all, if we give timely room, plenty of ventilation, shade, and keep our hives as cool as possible when swarming is likely to take place, the chances are ten to one in

from their usual place, and the folding wood quilt only is shown.

If the weather is hot at the time and the season not too far advanced, give a second crate of sections over the frames of foundation (with excluder zinc between to keep the queen down in the body of the hive). By this plan we give the returned swarm plenty of congenial work in comb-building, and the second stock, which receives the combs of brood, has the well-known advantage of "doubling" given to it, so that after the brood has hatched out honey can be regularly slung from the combs without interfering with the sections at work on the same hive.

Spacing Frames.—We have been asked for our opinion on distance pins and broad shoulders for frames, as a prominent bee-keeper has lately been giving his views on what he believes to be the best hive, and says, no doubt with perfect sincerity—"I use no distance pins, broad or under shoulders, as guides, as I can manipulate much quicker without them." We cannot understand by what method bees can possibly be manipulated in bar frames much quicker, when the regulating of the distance between each frame has to be attended to every time it is replaced, than if the form of the top bar was such that the frames regulated themselves. To make the matter clear—on opening a hive the first thing required is a little lateral space, so that combs covered thickly with bees may be lifted up freely without crushing. In our hive there is an inch play at the end, so we draw the divider back to the side of the hive without raising it, and we have the lateral space at once. If we wish to inspect a centre comb the intervening ones are drawn back close to the divider, not singly, but all at once, and they are replaced in the same way. In going over combs, each one after inspection is set in the hive again close to the divider nearest the operator, and when all have been examined one movement pushes frames and divider into their original position. If this is not much quicker than replacing frames one by one and regulating the distances between each as we go on, we are at a loss to know how the apiarian works. With broad-shouldered frames working on metal runners propolisation is never an inconvenience; with narrow top bars working in a rabbit it is an intolerable nuisance, as the bees have access to the whole of the space on which the frames should slide, and propolise it to such an extent that it sometimes runs down the very walls of the hive inside. This was one of our great objections to the use of the original Carr-Stewarton hive, which is made exactly on the same principle.

Conclusion.—The "Art of Bee-keeping" has been recently so fully treated of in the columns of the *Journal of Horticulture* by Mr. Raitt, that it would be a useless repetition for us to go over ground so well covered by the articles alluded to. In these "Notes" we have briefly referred to details in which the peculiar construction of our hive gives what we consider special advantages, so that in concluding our observations we may be allowed to summarise what has, we fear, been a somewhat disjointed statement of our experiences in designing what we consider to be the best hive for all purposes.

We have not taken into account the wants of a bee farm, and we have utterly ignored the interests of the British bee farmer (a mythical personage, often heard of but never seen). It is offered to British bee-keepers, who constitute the bulk of our apiarians, and whose stock seldom consists of more than half a dozen hives. These should be of good make, not worthless makeshift ones. They should give to the ordinary amateur bee-keeper the readiest way of making the most of our short honey season. The brood nest should be capable of enlargement or contraction with a minimum amount of trouble, and the brood combs should be accessible without disturbing supers. Spare frames should have a place to keep them in during winter, and doubling be possible without requiring an extra hive for the purpose. To the advanced bee-keeper the hive should be easily adapted for queen-rearing and nucleus requirements, and we confidently assert that the time and labour expended on a hive of our pattern will be well repaid in the possession of a thoroughly good bee habitation, which will answer every contingency that may arise; while for facility in hiving swarms, building up stocks in spring, supering, doubling, &c., and for warmth in winter and ventilation in summer it is all that can be desired.—W. B. C., *Higher Bebington, Cheshire.*

Fig. 15.—The Broughton-Carr Hive.

favour of success; and if (as in some seasons when a perfect swarming mania seems to take possession of the bees) if, as we say, swarms persist in issuing from hives with half-filled supers, they should be accepted and made the most of.

With the hive specially treated of in these papers, the following method of dealing with a swarm when increase of stocks is not desired will give a very satisfactory result. Hive the swarm in a skep as usual and place it close to the hive from which it issued. Remove nine frames of brood from the swarmed hive into a spare frame box, and after cutting out all queen cells and drone brood, give them to a second stock (which may be supposed to be already supered with a crate of sections) give frames of foundation in exchange for the brood combs taken away, and cover with the wood quilt only. Cut out all queen cells from the remaining nine combs, and while the sections are off, to enable the operator to do this, overhaul them and remove all that are completed, substituting empty ones instead. In the evening return the swarm to the parent hive by knocking out the bees on to the flight board as described on page 458 last volume. To make the illustration (fig. 15) as instructive and plain as possible to amateurs, the thick hair quilts are omitted

TRADE CATALOGUES RECEIVED.

James Yates, 29, Little Underbank, Stockport.—*Catalogue of Vegetable and Flower Seeds.*

Richard Smith & Co., Worcester.—*Catalogue of Garden and Flower Seeds.*
E. G. Henderson & Son, Maida Vale, London, W.—*Catalogue of Vegetable and Flower Seeds.*

James Cocker & Sons, Aberdeen.—*Catalogue of Vegetable and Flower Seeds.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (J. V.).—Mr. B. S. Williams' "Orchid Growers' Manual" is a reliable work; it is published by the author at the Victoria and Paradise Nurseries, Upper Holloway, price 7s. 6d., post free 8s. Nesbit's "Practical Land Surveying and Practical Mensuration," published by Longmans, Green and Co., London, are what you seem to require.

Address (R. G.).—It is so long since the Melon you name was raised that we quite forget the address of the raiser; moreover, it is possible that it is not the same as it was several years ago. If the information you seek is really of importance to you we will make inquiry on the subject. There is no book such as you seek, but you will find the particulars in our "Garden Manual," post free 1s. 9d.

Coal Tar (W. B.).—This and gas tar are identical, being obtained from coal in the manufacture of gas, hence the dual name.

Senecio macroglossus (S. H.).—Apply to Messrs. Veitch & Son of Chelsea, or Mr. B. S. Williams of Upper Holloway.

Jasminum nudiflorum (J. W., Pershore).—The above is the correct name of the shrub, and indicates the habit of the plant in flowering at a time of the year when the leaves have all fallen. Nudiflorum simply means naked flowers.

Peat for Lilies (Leamington).—The peat can be obtained at any dealer in horticultural sundries, as you will see from our advertising columns; and when ordering it you should mention the plants it is required for. Dr. Wallace's work on "Lilies and their Culture," published at Lion Walk, Colchester, would no doubt suit you.

Concreting Vine Borders (Cambrian).—A layer half an inch thick of sharp lime and cement, mixed like mortar, and spread on a firm level flooring of stones, will be quite sufficient for your purpose if the fall be 1 inch in a foot from the back to the front of the border. You will need drainage over the concrete. It is only under very special circumstances that we consider concreted Vine borders necessary, as we have found by experience that there are few cases where the roots of Vines cannot be kept near the surface by such treatment as was described in our columns last week by Mr. D. Thomson.

Making Tennis Ground (F. R.).—The number of worms in the soil indicates that it is rich rather than otherwise, and of a wet rather than a dry nature. If that be so, then a layer 2 inches thick of sharp ashes and lime, over this an inch of soil containing no worms, then the turves laid in sand, would in all probability not only give you a firm, dry, and practically wormless lawn, but the grass would grow quite fast enough for your purpose. If your park is very dry and poor the plan described would not answer so well, but in that case there would be few worms, and these might be dispersed by free applications of lime water.

Heading Down Dracænas (J. H.).—We scarcely understand your question, but presume you wish to establish the tops and exhibit these as table plants. You may do this at any time by splitting flower pots and fixing them round the stems, keeping the light porous compost in them constantly moist. There is no better time for doing this than when the plants are just starting into growth, and in a warm moist stove. Good for table decoration are the small-leaved varieties D. Sydneyi and D. Ernesti, which are both bright and graceful.

Grafting Pears (F. J.).—You may insert one scion in each branch, two if the branches are as thick as your wrist, and if both grow retain the best for the future branch, removing the other. As many branches as there are now, provided they are not much less than a foot apart, just so many you must provide for forming the future tree. The scions, well-ripened wood of last year, should be taken off at once and covered with soil or cocoa-nut fibre refuse on the north side of a wall to keep them fresh and retard their growth, as the stock should be in advance of the scions when the latter are inserted. It is much too early to start your Begonias and Dahlias, to which we will

refer more fully in a future issue, more urgent matters now requiring attention.

Pruning Roses (Truthful Gardener).—You would in all probability make a great mistake by pruning the Roses that are starting into growth so freely. If you examine the shoots you will find the buds near the base dormant. Thus they will remain, provided the present early growths are permitted to remain to "take the sap;" but if you remove these the lower buds would inevitably be forced into growth, and probably be destroyed by frost. The safe course is undoubtedly to defer pruning for at least another month, and possibly even longer, much depending on the weather in early March and the condition of the plants.

Cucumbers Dying (E. F.).—Information which you have not afforded is requisite to enable us to answer your letter satisfactorily. You do not say how long the plants have been bearing, but only that they continued fruiting until Christmas. If they were bearing heavily throughout last summer they are probably exhausted, and it is not likely they will again become vigorous. The only means of restoring them is to maintain a bottom heat of 80°, and to encourage the production of surface roots by periodical top-dressings of rough turfy loam and decayed manure, maintaining also a genial atmosphere and a night temperature of 65°, falling a few degrees towards morning, and increasing as much as possible by sun heat in the daytime. We suspect, however, the plants are exhausted, and you will do well to raise others promptly.

Propagating Sonchus laciniatus (A. S., Bedale).—If you have an old plant place it in moderate heat, and when it has started freely into growth take off the shoots about 2 to 3 inches long and insert them in pots of very sandy loam. Plunge the pots in a propagating frame, and be careful in supplying water until it is seen that the cuttings are making some advance; then gradually expose them to the air, and when well rooted and hardened pot them singly into a compost of turfy loam, sand, and leaf soil.

Aquilegia glandulosa (H. S., Bucks).—The description and remarks you mention were published in some notes by an experienced cultivator on the Aquilegia, page 53, vol. iii., July 21st, 1881. The particular species was thus referred to:—"With the lovely Siberian A. glandulosa we have experienced much trouble. At one time we concluded it was very delicate and could not endure our winters; now, however, we have altered our opinion, consider it quite hardy, and incline to the belief that it is of biennial duration only—at least this has been our experience in the London district. It well repays for all extra care and trouble; it grows in a tufted manner, and is dwarf in habit, seldom exceeding a foot in height. The leaves are triternate, segments coarsely lobed. Stems one-flowered. Flowers 3 to 4 inches in diameter; sepals nearly oval, very much larger than the petals, deep rich blue; petals the same colour, but tipped and margined with creamy white. It prefers a somewhat light and well-drained soil, but not peat. It flowers in May and June."

Amaryllises from Seed (E. E. E.).—The seed should be sown in light sandy soil and placed in a temperature between 60° and 70°, where, if the seed is good, germination will commence in about a fortnight. The plants will flower the second or third year, but they do not reach their best condition until about the fourth year, when, if they have been well grown, the bulbs will be strong. The number of good varieties obtainable from seed depends upon the quality of the strain. If the seeds have been gathered from carefully hybridised flowers of the best types in cultivation, three-fourths of the seedlings may be expected to be fairly meritorious, and some will probably excel their parents in size or colour of flower.

Cool House Orchids (Idem).—The following is a list of useful, distinct, and attractive Orchids suitable for such a house as you describe:—*Adiantum aurantiaca*, *Barkeria elegans*, *Cœlogyne cristata*, *Cypripedium insigne*, *Dendrobium Jamesianum*, *Epidendrum vitellinum*, *Lælia autumnalis*, *Lycaste Skinneri*, *Masdevallia Harryana*, *Odontoglossum Alexandræ*, *O. cirrhosum* and *Pleione humilis*. Some interesting particulars concerning cool house Orchids were published in this Journal, pages 240 and 241, vol. vi., March 22, 1883.

The Calabash Tree—Crescentia Cujete (Surrey).—The plant you mention is a native of the tropics of America, where it is called Tutuma. It attains the height of 20 feet. There are several varieties of the tree, producing various forms of fruit. These are from globose to bottle-shaped, and from 2 inches to a foot in diameter. The outer skin is thin and fleshy; the shell is hard and woody, enclosing a pale yellowish soft pulp, in which are embedded a great number of flat seeds. When the pulp and seeds are removed, and the outer skin taken off, these shells are used by the natives for all sorts of vessels; and some of the long small-fruited kinds serve for spoons and ladles. Some are large enough to hold a gallon, and as they stand the fire well they serve to boil water in. The thicker parts are used as button-moulds. The Caribs engrave the outside with a number of grotesque figures, which they sometimes colour black or red. The pulp is sometimes eaten, but is not agreeable, and is sometimes used as a poultice; a syrup made of it is esteemed by the natives for disorders of the breast, in contusions and inward bruises. The wood is very tough and flexible, fit for coach-making, and is frequently used for making saddles, stools, and furniture. The leaves and branches are eaten by cattle in times of scarcity.

Employment at Kew (Querist).—To obtain a situation at Kew you should write to the curator, Mr. John Smith, stating your desire and where you have been employed. Forms will then be sent to you, and, if these be filled up satisfactorily, your name will be placed on the books to await your turn for a vacancy. With steady perseverance you may there acquire much useful information, which, if judiciously applied, will be of great service to you in after life. "Colenso's Arithmetic," published by Longmans, price 4s., is a standard work. Tables of the French weights and measures are given in "The Gardeners' Year Book," published at this office, price 1s.

Ferns for Unheated Fernery (L. W.).—Besides the choice species and varieties of British Ferns the following would probably succeed in your very mild climate:—*Cyathea dealbata*, *Dicksonia antarctica* and *Blechnum covadense* as Tree Ferns; also such exotic Ferns as *Adiantum pedatum*, *venustum*, *cuneatum*, *formosum*, *reniforme*, *colpodes*, and *tinctum*; *Asplenium eburneum*, *biforme*, *bulbiferum*, *dimorphum* and *reclinatum*.

Cyrtomium falcatum, and Lastreas intermedia, marginalis, and many others; Nephrolepis exaltatum and tuberosum; Onychium japonicum, Goniophlebium appendiculatum, Pteris argyrea, cretica albo-lineata, tremula, and umbrosa; several Polypodiums, and such Selaginellas for margins as denticulatum, also Wildenovi and umbrosum. We know also that the climbing Fern Lygodium scandens which is generally grown in a stove will succeed if planted out in your cool fernery, as also will the beautiful new Fern Lomaria discolor bipinnatifida. Those and many others are worthy of trial, but as you do not state the number you require we can only give you a suggestive list.

Destroying Woodlice (F. H.).—There are various ways of destroying them, the most wholesale plan being to place some pieces of boiled potatoes near to the places they infest and cover with a little hay, and in the morning pour boiling water over the hay. Another plan is to wrap a boiled potato in a little hay very lightly, and place it in a flower pot laid on its side near to where the woodlice congregate or commit their depredations, and the following morning shake the pests from the hay, in which they will be secreted about the bait, into a bucket of boiling water. Repeat for a time, and the pests will be reduced so as to do very little injury. Parsnips boiled nearly soft, cut into slices, and dressed with arsenic form deadly baits. These, if placed where the insects abound, will reduce their numbers considerably. It is, of course, necessary to so place the poisonous baits that no accident can possibly arise by their misuse.

"The Gardeners' Year Book and Almanack" (B. L., Liverpool).—You have made a serious mistake. This almanack is quite correct, and the 29th of February is not omitted. The mistake, and it is presumably unique, occurs in another work that is not published here, and in which as you say, "Lady day, Michaelmas day, Christmas day, and the year ending on a Tuesday instead of on Wednesday are all wrong." We have referred to the work, and find that in consequence of the strange omission indicated the calendar is inaccurate from the end of February to the end of the year. It is easy to make mistakes, as your letter proves, and we must request that you will be more careful in your assertions; and, further, we must ask you to promptly correct any similar misstatements that you may have made publicly or privately elsewhere.

Vines Unhealthy (A Lady).—We are obliged by your letter, which clearly describes the condition of your Vines. Their state appears to be precisely as we anticipated. They have been seriously overcrowded, no doubt overcropped and half-starved by the want of water—in a word, they have been grossly mismanaged, and we fear nearly, if not quite, ruined. You can find few or no roots in the border, because they have been driven downwards, and probably into the subsoil in search of the moisture that was denied them near the surface. The support they sought was not found, hence the flagging of the foliage. The person in charge on observing this applied what he conceived was the proper remedy, but he commenced at the wrong end—namely, by limewashing the glass instead of watering the border, which you observe is inside the house. He was not a gardener, even if he considered himself one, and probably did not read the Journal, or if he did, read skimmingly, slightly, and profitlessly, for such readers we fear there are. As to the renovation of the Vines, you cannot do better than follow as exactly as possible the practice described by Mr. D. Thomson in the last paragraph but one of his very useful article on page 58 last week; but in addition, if we found the soil in the lower portion of the border containing the roots very dry, we should soak it with water, and the dry roots would the sooner emit fibres into the fresh soil and manure, which must be kept regularly and decidedly moist, and not much water will be needed for this provided the surface of the soil is well mulched as directed. The rods we presume are pruned now, the laterals being shortened nearly close to the main rods, or to the lowest good bud on each lateral. The next process will be disbudding. Remove gradually the buds as they start, reserving only the stronger and more promising to form shoots from 15 inches to 18 inches apart along each side of the rods. Allow these to extend for a length of 2 feet, then pinch off afterwards all sub-laterals as they form at one leaf—that is, as soon as a leaf forms as large as a shilling, nip off the shoot just beyond it. By adopting this practice, maintaining a genial atmosphere, keeping the foliage clean, and ventilating the house judiciously, especially admitting air during the spring and summer very early in the morning, you will, we hope, secure stout laterals and well-developed foliage. This accomplished, and not till then, can good fruit be expected. Do not force the Vines, but allow them to start naturally, as forcing Vines so exhausted exhausts them the more. We trust our reply will be useful, and you are quite at liberty to write to us again if you need further information either now or as the season advances. We may add that the laterals you sent were microscopically examined, and contained practically no "stored-up food," while well-nourished and matured canes are crowded with starch granules.

Names of Fruits (Fred Scott).—1, Rymer; 2, Winter Greening; 3 and 5, Not known; 4, Ten Shillings.

Names of Plants (P. G. H.).—We have repeatedly stated that we do not undertake to name more than six plants at one time. 1, Ceanothus rigidus; 9, Berberis Darwini; 10, Garrya elliptica; 11, Veronica speciosa; 12, Thujaopsis dolabrata; 13, Ligustrum japonicum. Some of the others were not in suitable condition for naming. (X.)—Unrecognisable, the flower being quite dried up in the cotton wool.

Erratum.—In the article on "Plant-forcing" in the last issue of the Journal (page 66), for "hotbed of loam and stable litter" read "leaves and stable litter."

COVENT GARDEN MARKET.—JANUARY 30TH.

TRADE keeps quiet, Grapes scarcely maintaining their value. Cucumbers lower. Kent Cobs stagnant.

THE WELSH BREED OF CATTLE.

(Continued from page 76.)

ALTHOUGH the cattle are reared as natives in many parts of Wales in mountainous districts, yet it is affirmed that their docility is remarkable. A stranger may walk safely into a herd of cows, but it is not safe to do so where there is a bull unless accompanied by some person acquainted with its habits. Bulls after they are one year old should always be kept in the house, not only avoiding accidents, but enabling the farmer to regulate the times of calving. The best quarters for a bull is that which we fully explained a short time ago in this Journal when writing on the improved dairy cattle in November last, when the advantages to the farmer and his safety, together with the benefit of the bull were fully explained. The Welsh cows are so gentle that they stand well to be milked in the yard or in house, and with their large, full eyes and quiet expression look the very picture of docility. They are, as it is stated by Mr. G. T. Bowden of Gomer, near Derby, a celebrated breeder of these cattle that never ties up any of his cattle excepting those which he milks and finishes off for the butcher. The calves when reared on their dam's milk at one year old are as big, with better hair and coats than those reared by hand at two years old. Other calves reared by Mr. Bowden live on skim milk, Simpson's calf meal, and a little dissolved oilcake. For feeding purposes it is considered best to buy barren heifers and bullocks turned three years old. These points prove at once that these cattle are not behind the best stock of this country when treated in a generous way.

With the view of fairly representing the worth of the Welsh breeds we will now give what is stated in the Journal of the Royal Agricultural Society by Mr. Algernon Clarke. He says that according to Mr. Morgan Evan, one of the best authorities on the subject, "The colour of the Pembrokeshire or 'Castlemartin' is black; the horns are of great length, yellowish white tipped with black, wide spreading and curving upwards; the head is of medium length, longer than the West Highlands, but somewhat longer than the Devons, approaching the Herefords or the improved Sussex in form. The nose is small and the neck fine, with little tendency to "throatiness" in some breeds; the eyes are prominent, but without the untameable gleam of the West Highland or Chillingham cattle, domestication having removed any special traits of wildness and of ferocity; the coat is long, not straight like the Highland cattle, but wavy, or sometimes curly; the forehead is broad. Several writers have remarked on the colour of the skin as being of an orange-yellow, and the coat on the barest part of the body as being of a brownish hue. Some of the best breeders in Pembrokeshire are careful to maintain this characteristic in their herds. This, along with a yellow horn and a wavy coat, almost invariably indicates a beast that will feed well either on grass or in the stall. A short, crisp, coal-black coat is not to be compared with one that is long and wavy. The meat produced by these cattle is excellent, and not to be surpassed in texture and quality. The milking properties of the cows are certainly equal, if not superior, to those of most modern improved breeds."

Mr. Evans also says, "Welsh black cows are on the average equal to any class of cows in milk-producing capabilities. Taking into account the climate, soil, and average homestead accommodation in the county, the Pembrokeshire cattle can be bred to feed cheaper than Shorthorns or Herefords. Attempts to improve the breed by crossing have not been attended by success, though the Devons amalgamated best." Again we find it recorded that "the Anglesea cattle are very

like the Pembrokeshire; also that the head of the ox is very frequently heavy and bull-like. Davis in his time attributed the bull-like features in the head and dewlap "of the Anglesea ox to the fact that the calves were not weaned in Anglesea until double the time which they are weaned in other counties, together with their not being gelt until they are about a year old."

With the latter fact we quite agree, for in practice we go farther, and contend that they should not be castrated at all when required for sale at early maturity. They must of course be kept quiet in separate boxes, and never used for stud purposes, and then the animals will yield a very high rate of weight for age of excellent quality, especially if slaughtered at about eighteen or twenty months old, for they will be heavy enough in the carcase to meet the best consumers' requirements, and eat like ripe old ox beef. It must be remembered that to carry out this idea we have in such a case always kept the animals at full head, commencing as fat calves, and never losing this condition; then in comparison we have obtained a large percentage more beef from animals never castrated than from steers, each being kept alike in food and accommodation, and killed at about eighteen or twenty months old.

We have given several quotations from breeders of the Welsh cattle, and although some little difference may be observed in their statements, yet it is no more than may be expected from the difference occurring in raising the cattle under varying conditions, and of selection by the breeders, as well as the influence of soil and climate. Although the principality of Wales is not very extensive, yet the mountains and valleys, together with seacoast conditions, are surroundings which effect as much variation in style and type of the Welsh cattle as it does in other breeds under the like circumstances throughout the kingdom.

We will now quote from the last Smithfield Club report of the *Agricultural Gazette* of December 17th: "The weights of animals at Islington were considerably higher than at Birmingham. The monstrous Hereford cow Giantess with her family won attention and prize money at Reading and York, came to Islington to find herself as to her weight behind a Shorthorn cow of Lord Sudeley's breeding, a descendant of Mr. Wetherell's branch of the famous tribe of Sockburn Sall. The only beast heavier than this cow (which inherited through her sire the size and character of the Winsomes at Holker) was a gigantic Welsh, which weighed 22 cwt. 1 qr. 6 lbs. at three years eleven months two weeks, and was far from being fat. He might be made (did public opinion favour such displays) to weigh a ton and a half if kept to the age of some Highlanders, of which more than one exceeded six years old. It was not difficult to see at Islington that numerous as are our breeds of cattle now, there is yet material among them to form more."

This last allusion applies most appropriately to the possibilities of what science and practice with great experience may effect in the breeding of Welsh cattle. It is also reported that the Welsh breeds at Islington were in rather full entry. Major Henry Platt's North Wales steer, to which we have referred as to weight, &c., which took the breed cup, was of gigantic size and weight of flesh, with more of size and symmetry and beautiful quality than is sometimes seen in the character, style, and type of the Welsh animals. The fact of this animal having taken the breed cup, together with his symmetry, quality, and enormous size, must, to the mind of every experienced cattle breeder, with the conviction that the strain from which this animal descended may by careful selection in breeding be made the basis of a race of animals valuable as milking stock and capable of yielding, at weight for age, carcasses of beef not to be exceeded in weight and quality by any other breed of cattle.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—The busy time for sowing pulse and Lent corn should be anticipated, so that any work which can be done with the horses may be attended to now or at any other time when it will prevent the displacing of horse labour in tillage work at those periods. Our busiest periods may be said to occur at the seed time for Lent corn, Beans and Peas, early Potatoes, Mangolds, and Cabbages. The next time when all hands will be employed, as well as horses, is the haying time, which in some districts lasts from the second week in June until the corn harvest commences; which, in the case of an early harvest and sometimes in the event of a late one from adverse weather, usually delays the ripening of the corn, and also delays the haying time. In the grazing districts of various parts of the kingdom the question of ensilage is becoming of extreme importance, because if the silos are properly constructed the materials placed in them will then be secure from injury. The question of haying will thus be reduced to a minimum, for ensilage can be carried in any weather with ordinary care. Nor is it necessary in certain soils to have an expensive silo built, for a farmer from America has stated to us that they used any dry soil for a silo by digging a pit of the required dimensions and placed their Maize and green fodder, properly weighted, in pits with the sides formed of the bare soil. In this way, also, they place their Potatoes and other root produce, although not in such large bulks as they do of Timothy Grass

and other green produce, and without being weighted, but merely covered with a little earth and thatched with any material like straw or haulm, and shaped to shun the water on the surface by a small trench dug round the outside to carry off surface water caused by the rainfall, melting of snow.

Hand Labour.—Forking cut grass wherever there is but little may now be done by the women; but in some parts of the country women as field workers are still available, while in others they will not work at all in the fields, except perhaps in haying and harvest time. Hedging and ditching may still be done, but especially the dead hedges, which are much required on the chalk and limestone hill districts. All the hardest and most lasting wood is reserved for this work, with white and black Thorn hushes for filling in between the stakes and ledgers. There is an old saying that "an Elder stake and a Yew ledger will make a hedge to last for ever." The weather has been very favourable for planting orchard trees, which is now completed; and in any case in the rural districts the orchard land should be wired in with wire netting—at least where young trees and bush fruit trees have been recently planted, a protection against both hares and rabbits.

Live Stock.—Sheep feeding off roots on the open fields are doing better than usual, and this will tell in favour of the land when sown with Lent corn, as well as the benefit of the sheep; for in some years past, especially the winter of 1882-83, the land was so sodden with rain water and so trodden by sheep feeding on the root crops that it not only required much extra horse labour in tillage before seeding with Lent corn, but that any Barley grown on such land did not, as a rule, prove a malting sample or a full crop. Cattle now feeding in the stalls should have only a moderate allowance of roots—say of Swedes 70 lbs., of Mangolds 56 lbs. per day, and it is much more economical to reduce all corn or cake given them into meal, to be mixed with cut roots, and also more healthy for the cattle. Much has been said on the subject of quantities of oilcake and corn per day. We, however, do not exceed the use of 4 lbs. of best linseed oilcake and 2 lbs. of bean or barley meal per day. We never give hay, but only sweet straw of Oats or Wheat *ad libitum* loose in the racks, the residue or unconsumed portions being used for littering the pens. As a rule, a bullock will not make more than 10s. per week increased value. Let the home farmer calculate the cost of the above-named food and mode of feeding, and it will be found that the advantage or profit is not more than 3s. per week; but in case of hay-feeding instead of straw it will absorb 2s. 6d. of the otherwise profit, whereas the cattle will be much healthier on straw-feeding than when feeding on hay. We have frequently had cattle refuse their roots whilst eating hay, but never when feeding on straw.

OUR LETTER BOX.

Sowing Seeds for Pasture (J. R.).—If your land is clean where you have dug in a crop of Mustard, it must be allowed to remain until dry weather in March or April, then work it down by harrowing and rolling until perfectly fine on the surface. It will be better not to dig the land again; if it should be hard let it be horse-hoed with the points, this will bring up any unbroken portion, which may be reduced to fineness by harrowing and rolling. If it is intended for permanent pasture you will require about 3 pecks of mixed grass seeds for a quarter of an acre. The ready-made mixture of sorts of grass seeds can be obtained from the firms you name, but you should state the nature of the soil and the object of laying it down. If sown with Barley 2½ bushels per acre. The seeds of grass will only require ordinary weeding, and the Barley crop will pay, independent of the grass requiring no attention until after harvest. If sown alone in April the weeds will be a torment all the summer, and will render necessary the mowing of the grass and weeds together twice during the summer. We prefer sowing the seeds with the Barley, which will protect the young grass plants and prevent injury from weeds until the plants are strong.

REMARKS.

20th.—Sunshine in morning, rest of day dull; drops of rain about 9 P.M.
 21st.—Fine all day, but not very bright.
 22nd.—Windy all day with rain, and a gale in evening.
 23rd.—Wild wet morning; violent gale all day.
 24th.—Bright throughout; rather good sunset.
 25th.—Fine till afternoon; violent squall, with rain and hail, at 4.40 P.M.; lightning at 5.45 P.M.
 26th.—Squall at 4.30 A.M.; dull morning; wild afternoon, with rain; gale from 5 to 9 P.M.; lightning in evening.
 Probably the most windy week for many years past, the gales of the 23rd and 26th being of extreme violence; the latter characterised also by the exceptionally rapid rise of the barometer as the centre passed this station—viz., 0.06 inch in eight minutes from 7h. 33m. P.M. to 7h. 41m. P.M., or at the rate of 0.45 inch per hour. At Isleworth occurred nine minutes earlier, and was at the rate of 0.43 inch per hour.—G. J. SYMONS.

LOOKING BACK.

HE labours of cultivators and hybridisers have been devoted to improving the wrong Potato."

Gad zooks, sir! and now after a tolerable life's work in striving to improve our chief esculent, *Solanum tuberosum*, what can I say in answer as I read the above extract at page 58? The "if," at any rate, may be read large at the beginning of the paragraph. It was only the other day, at a committee dinner at the Crystal Palace, whilst conversing with my friend Mr. Douglas about Potatoes, I said I had "run to the end of my tether," and done what I set myself to do from the beginning—crossed and handed down the concentrated blood, so to speak, of all the best of our good old English kinds, and of late years re-crossed again with the best of the new American sorts, till I have achieved to disease-resisting varieties as near as may be, with early proclivities, good bearing and keeping properties, and to flavour all that can be desired; and lo! just as I am resting on my oars, and consoling myself upon having set my footprint upon the sands of time, I read your leader, which tells me of a Potato that has been lying *perdu* at Chiswick and Kew to prove that we have all along been wrong! But—I have allowed you the "if"—it has yet to be proved that this *S. Maglia* will cross with *S. tuberosum*. I hope it will, as it will relieve us from sighing for "new" Potato "worlds to conquer." It is just the ground we must start afresh upon; but it is not exactly new to me, as I tried for four consecutive years to cross *S. Fendleri*, a New Mexican species, with our English varieties and failed, which gives me reason to say that we must not reckon too surely upon *S. Maglia*. I not only failed myself in crossing *S. Fendleri* or inducing it to seed, but it proved also unmanageable with a gentleman (a correspondent, I believe, of Mr. Baker) in America, and I think it may prove interesting for your practical readers if I resuscitate some letters with my answers immediately treating upon the subject.

"Charlotte, Vermont, U.S.A., January 5th, 1876.

"To MR. FENN,—It seems desirable that I should employ your beautiful and excellent seedlings to give to our strong-growing American sorts finer quality and flavour; and probably, if there may be any object in doing so, you might on the other hand, by an infusion of American blood into some of your seedlings, increase their yield, without, it is to be hoped, materially impairing their high quality.

"Twenty years ago there was little disparity, as I suppose, between English and American Potatoes. The majority of the varieties which we now employ, or certainly those which are grown most extensively, have originated since that time, and have descended from semi-domesticated varieties imported from South America. Thus from such an one Mr. Goodrich got the Garnet Chili; from the Garnet Chili Mr. Breese raised his seedlings, the Early Rose, Peerless, Breese's Prolific, &c.; and, impregnating the Early Rose with pollen from the best of the old sorts, I obtained the Snowflake, Alpha, and Ruby.

"The advance made from generation to generation in this line by such a course of seedling is very marked, and gives ground to hope that if the work be continued, especially in the manner I have suggested, we shall ere long attain to perfect results, possessing ourselves of varieties which will combine high quality and fine appearance with satisfactory vigour and productiveness.

"I have named and put in commerce only the three seedlings
No. 189.—VOL. VIII., THIRD SERIES.

mentioned above. They have been selected from many hundreds. The first and second you may possibly possess; the third is only to be sent out for the first time this year, though it was at the International Exhibition at Alexandra Palace, and with others received a certificate of merit. Besides this, I have many seedlings raised last summer, some of which are of very fair promise. Any of these (and a packet of the hybridised seed which I shall sow the coming season, should you care for it) I will be glad to send you in exchange for a selection of your favourites, such by preference as will furnish good pollen. The pollen of nearly all our newer American sorts is utterly ineffective (with the Snowflake sterility carried so far that the flower buds very rarely open, but fall away early), so that it is only as seed-bearers that they can be employed in cross-breeding.

"Hybridisation of species has been one of my aims. Besides the original species from the Andes, *Solanum tuberosum*, I cultivate one very distinct from our western territory of New Mexico, *S. Fendleri*. As yet all my pains taken to impregnate it with pollen of the cultivated species has proved unavailing, though partially developed fruits have followed my operations, only to fall away, however, before maturity. When I learn the conditions which the plant requires and more fully meet them, I shall succeed, doubtless. I think I have given the real cause of my failure, because the plant is unable to set its own fruits with me.

"Peru can furnish us still another species, *S. montanum* (vide 'Bot. Mag.'), and I am very desirous to obtain it.—I remain, yours sincerely
C. G. PRINGLE."

"January 27th, 1876.

"To MR. PRINGLE,—I seem already to have entered into your ideas concerning the minglings of blood of English and American kinds. For three years consecutively, though as yet ineffectually, I have tried to cross my Rector of Woodstock seedling with your Snowflake, as being the very best of the American varieties yet sent over to us. Snowflake refuses to produce me a globule of pollen or to become impregnated. For the latter I do not care, as I desire your seedling to become the male parent, in order more certainly to infuse productiveness; Snowflake refuses *in toto*. This also has been the case with the other American varieties, till this season a stool of that shy bloomer Willard's Seedling threw a stalk of flowers, and to my great satisfaction gave me some pollen upon my thumb nail. I immediately applied the dust to the pistils of three prepared florets of my seedling Bountiful, and in a few days I had the inexpressible satisfaction to find impregnation complete, and the berries sturdily swelling.

"Again, three years ago, after applying the pollen of Bountiful to some hundreds of pistils on the blossoms of the American Late Rose, I was in despair till two farewell bunches of flowers appeared in the row, when as a last resource I again applied the pollen of Bountiful, and perseverance gave me five impregnated berries. This circumstance revived my hopes in Snowflake, and I intend through this season to watch for her tardiest flowers, and so on to try and achieve successful impregnation with Rector of Woodstock. I sowed the seed of the above international crosses, and I have now by me 400 seedlings verging from dark red though every intermediate shade up to pearl white, and from perfect rounds to the handsomest types of kidneys—no eyes to be seen upon the majority of them—a more promising batch of seedlings I have never raised. Now, if in my object I shall have infused English flavour, and maintained the superior cropping qualities of the American varieties, I shall have fore-wrought-out your suggestions in the second paragraph of your letter. May it prove so! (Mem., 1884, it has).

"Twenty years ago Potatoes were "much of a muchness," both here and with you. Nearly as long ago I crossed our old red Regent, with a transatlantic sort called the American Black Kidney. This, my first artificial cross, proved very prolific, but of no use, not one of the 500 progeny was equal in flavour to the male parent, the Regent. One of the seedlings became a favourite with the cottagers about here (mem., 1884, I then resided at Woodstock), and another I kept as a breeder for good form, though with a bad internal stain, which it persists in handing down to posterity. I will send you a few of both, though not for distribution, merely to show you the result of a new idea wrought out long ago, and what came of it. There is, however, a variety lately come into commerce here called Blanchard, certificated by our Royal Horticultural Society, which very nearly indeed resembles my Purple Blush, the Anglo-American cross first mentioned. The other I call Cricket Ball; perhaps in your soil the internal stain may disappear. At any rate, you will see I have begun to cross-breed again with your new semi-domesticated varieties, and because of their differing from your old sorts I feel almost certain of attaining to better results, and thus exhaust the purport of your third and fourth paragraphs.

"I observed your new seedling, Ruby, at our International Exhibition, but I abide by Snowflake, as I want to get a good white cross from it. Let me beg to propose for you and me to work in concert thus:—Cross Snowflake with Rector of Woodstock, and *vice versa*, if you can. Cross Bountiful with Willard's Seedling, using the latter for the male parent only. With Snowflake cross Rector of Woodstock, and we shall be both aiming at the same results for after comparison, and for certain comparative results, by your adopting the latter procedure with the two others which I have accomplished. Then we shall be able to decide, without further beating about the bush, on which side of the Atlantic a real improvement lies. This will do for the present I think. In regard to your fourth paragraph, as I dare not for conscience sake request more of you, when I read of "those others" of the Andes and New Mexico that you propose to test, I must rest on my present oars for a year or two, as I have

nearly 100 of my assorted four-year-old English varieties now under their final probations.

"Apropos of Peru. Amongst the batch that the parents of Bountiful produced (Fenn's Onwards by Early Emperor) was a peculiarly odd-coloured seedling with crumpled foliage, which for its oddity I took up to our Royal Horticultural Society's Committee-room at South Kensington, but merely to find that its exact prototype was there exhibited, and growing in their garden at Chiswick, from tubers they had had sent them that very season as a wildling from its primitive habitat in Peru. I hope you will be able to procure *S. montanum* from thence, though, for my part, in regard to the creation of novelty, I would pin my faith to new species, such as *S. Fendleri*, from New Mexico, for had not our old English and American, and our present semi-American species and varieties their origin in the signs of the Andes, Peru, and South America?"

"In conclusion, allow me to propose to send you, without waiting for your answer, some seedlings of mine that will interest you, including Bountiful and Rector of Woodstock, to carry out the above proposed crosses.—ROBT. FENN."

"Charlotte, Vermont, U.S.A., June 27th, 1876.

"To MR. FENN,—Numerous botanical expeditions among our mountains into our deep dark swamps and along the shores of our lake almost constantly occupying my time, have been allowed too long to prevent the acknowledgment of the receipt of the second box of Potatoes you were so good as to despatch to me. The first sending has never been heard of on this side; but this last one reached New York in due course, and after some delay in our Custom House arrived here in time to be planted June 7th.

"Thanks to your very careful packing the Potatoes bore the long journey without any detriment. I planted them with great care, and they appeared above the soil in a remarkably short time, and since then have pushed on rapidly. While the greater part of the collection was placed in my own grounds, seed of several sorts was sent to the mountains to enlarge the collection which I am having grown there, where, if I fail at home to get the crosses we so much desire, I shall, as I have great confidence to believe, realise success.

"You mention the Willard as the only one of our new strain of Potatoes, these lately descended from the wild or semi-wild South Americans, which gives you good Potatoes. Except its mother, the Early Goodrich, and the very wild larger white of Mr. Goodrich, I know of no others similarly fertile. I have been compelled to rely on the old strain of Americans, some of which are very productive. The Excelsior I have used oftener—it is the pollen parent of the Snowflake. It bears fruits very profusely, is a great cropper, and is, as our Potatoes go, of best flavour and quality. It would surely give your seedlings vigour, and in a little tin box, to go by sample post with this, I send you a small tuber of it, numbered 2. With it are three little tubers of *S. Fendleri*, which though so very small, are nearly of average size. Under the numbers 6 and 8 I also include two grandchildren of our excellent Peachblow; their mother was a beautiful white kidney of fair quality, which was originated at London, province of Ontario, Canada, and is called London White. I send these two tubers because the sorts are very strong growers and will supply you with the most potent of pollen.

"And how I should enjoy leading you along the sinuous shores into the deeply indented bays and around the towering wooded headlands of this lake of blue waters, or over the green glades and darker Fir-clad hills to the mountain summits—patches of the soil and flora of Labrador or Southern Greenland lifted up in our midst a mile above the sea! You would perceive a fitness in the name of our northern State.

"But if such pleasure is denied us both I beg you to believe that your friendship is deeply appreciated here, and the kindness and patience with which in the very busiest part of the year you met and so fully satisfied my requests.—C. G. PRINGLE."

I have not yet learnt how the Potatoes behaved in Vermont. I still live in hopes of doing so, and I will now, with your permission, let your readers know how the Potato world has wagged with me in regard to my Anglo-American seedlings:—Suttons' Early Border, Early Regent, Fiftyfold, Reading Russet, and Prizetaker, are the commercial results of the American Willard and Late Rose crosses with my Bountiful. Two years after I came here I had the very great satisfaction to secure a few globules of pollen from Mr. Pringle's American Snowflake, from a bunch of late blossom in my garden, so late indeed that the flowers of the Rector of Woodstock were over, and in short every other blossom for all my sorts, excepting by great good luck a couple of late florets, which were unfolding upon a stalk of a condemned seedling of the Willard by Bountiful. I never impregnated more carefully, or more nervously, than I did those two blossoms, and my anxious wish at the time was that they had belonged to Rector of Woodstock. At any rate I had got the pollen from the right source. One only of the berries swelled and ripened the largest Potato fruit I ever saw. It produced me fifty seeds, every one of

which germinated in the following season. This has proved a very good disease-resisting cross, giving to commerce Suttons' Ringleader, Favourite, and Lady Truscott; also, gone into stock for another year, two seedlings provisionally named Golden Spot and New Bountiful. The Royal Horticultural and Crystal Palace certificated Alderman De Keyser I hold in my own hands for the present, along with a few others of the batch, to undergo further probation. Thus ends my Potato history up to the present.

I am your oldest living correspondent, or I would not presume to become a teacher in your pages at this time of day, although, when I think of the old ones and look at the young ones, there is not much reason to call each other names. We all did, and you all are doing good. *Esto perpetua*. I think, though, I can impart a few words of advice anent the Potato. Doubtless an extra fillip will be given to the cultivation of the esculent now that the Cinderella of Nature is countenanced by nobility, and the savants have questioned our doings. The outcome of the popularity that our Potato shows have engendered is to have created a legion of breeders of the esculent by crossing—I fear indiscriminate crossing. The Potato, like everything else, must be served an apprenticeship, so to speak, and, simple as it may appear, it has been a long and expensive study for me. I find, too, my seedlings are being extensively used for cross-breeding at haphazard with any variety. Now, I cannot do so myself without knowing it would deteriorate their quality. Size and appearance may be so gained, though almost invariably at the expense of quality. Whoever rises from my shoulders I should like them to rise to something better; to breed from my seedlings at haphazard is to go backwards instead of forwards. It can only be done by the careful study of what has gone before, and how improvement is to follow. Magnum Bonum may be quoted as a special gift of Providence—a natural seedling raised by Mr. Clarke, and, happily, though quite by accident, introduced to commerce, a circumstance that very rarely happens. My seedlings seem to have been considered for the nick of time, and for the "new species" seem to have been especially prepared; and in the very breath as I expressed myself at not seeing my way to any further improvement, so far as my particular hobby was concerned, up rises *S. Maglia*, *S. Jamesi*, &c., and to these, coupled with Mr. J. G. Baker's recommendation, I would earnestly turn our young hybridisers' attention.—ROBT. FENN, *Sulhampstead*.

FRUIT-FARMING AND JAM.

AT a moment when so much is being written and said as to presumed fabulous profits to be made by fruit-farming, gardeners, fruit-growers, and the readers of the *Journal of Horticulture* generally, are deeply interested that a subject so identified with their interests should be thoroughly ventilated. Who will question this when we see the leading politician of the age, resting from his labours of tree-felling at Hawarden, seizing the subject and rushing with it to the front with his usual vigour of advocacy? Lord Sudeley has embarked in planting an estate of 500 acres with fruit trees; others, we are told, are entering the lists, and a golden era of profit is assured as being in store for all who embark in similar enterprises. It is most important for the country that the subject should be truthfully dealt with, as there is no doubt that we are equal to growing sufficient fruit for all our wants, so also that far-seeing men are trying their best to meet them, though, as it seems to many, with but thin prospect of profit.

Few persons are aware that in the last season Herefordshire alone grew a crop of Apples, much of it choice dessert fruit, second to none in the world, and sufficient to have met the entire wants of London and other large cities, and yet but a small proportion of it left the farms on which produced. Thousands of tons of beautiful dessert and culinary fruit were converted into cider, and probably an almost equal quantity was allowed to rot under the trees, simply and entirely through the high rates exacted by the railways for its conveyance. The same, though to a more limited extent, occurred in other counties. It takes on an average a bushel of Apples to make a gallon of cider. So great was the quantity manufactured that casks sufficient for the storage could not be obtained. Sixpence per gallon at the farm door is a fair average value of the season's

product, which, without allowing anything for labour and casks, places the fruit value at 1s. per bushel.

Now, why was this fruit not sent to London? Simply because the railway rates for its carriage, together with the exactions of dealers and middlemen, have in previous seasons proved to the growers that loss rather than gain would result from so dealing with it. As a rule farmers are ready enough to go into the culture of vegetables and to multiply poultry with view to egg-production, and even to turn their attention to jam if any reasonable chance of profit exists. Such of them as have tried the two first-named panaceas have, to their cost, found that after sending the Cabbages and Cauliflowers to market, the lords of the railways generally gobbled up all the market proceeds. Jam, it is true, has yet to be tried. Wary ones, however, have well-grounded fears that the railway demand for carriage of the pots alone, preparatory to filling, would absorb a big slice of the yield from the product.

Sad indeed is the condition of the British farmer. On every hand Seylla or Charybdis seems before them. The cattle disease is stalking throughout the land, yet it is at such a moment Mr. Gladstone tells farmers to go and make jam. Surely this is a day for other and more friendly searching counsel. Might they not have been more wisely directed to railway reform? Under the existing pernicious system foreign farm products are conveyed at through rates from foreign far-off places to London and other large seats of consumption at greatly lower sums than the mileage rates he is charged, and thus the British farmer is driven out of the field. He does not object to foreign competition fairly conducted, neither would he lessen the abundance to his brethren in the towns. He does, however, feel the hardship and injustice of being shut out of his own markets by iniquitous preferences given to his foreign competitors.

It is not only on fruit and eggs that the railways are extortionate. The farmer is practically shut out from receiving dung from the cities and other fertilisers from a distance. Lime and salt, so beneficial on certain soils, are often weighted as if they were gold dust; and as to feeding stuffs for cattle, these are conveyed only as though intended for the farmers' table rather than as the material of meat product for mankind. It costs from 25s. to 30s. to move a ton of linseed cake from the great emporium of Liverpool into parts of Sussex, a service which in America would be done at less than one-third this cost. What chance has the British farmer to meet rent, crushing local rates, tithes, and Government taxes in the teeth of such handicapping? The thing is hopeless. After long years of fruitless remonstrance and striving against the wiles of railway executives, it is evident that nothing short of permanently establishing the Railway Commissioners with full powers to control the complained-of exactions will meet this great national evil. The existing race of railway managers, however able they may be in conducting costly parliamentary fights at Westminster, are, for the most part, of a school of the past. Men who have striven to discourage third-class travelling, now seen to be the most profitable business, and who, in such instances as that of the Brighton line, have done their utmost to drive this class into vehicles of a worse description than their old style of cattle trucks, are hardly the men to see these questions in a true light.

Fruit-growers are buoyed up with hope that the more extreme exactions of the railways will be cured when the Railway Commission is reconstituted and its powers extended so as to restrain the impolitic action of the Committee in obstructing everything that tends to agricultural helpfulness. The farmers in America are not so dealt with; they have secured for themselves justice and fair dealing. What would be said for a rate of 15d. for the carriage of a can of milk of thirty gallons 128 miles? Such is the charge on more than one railway in America.

It would seem impossible that the present rates for fruits, farming produce, and farming needs, such as manures, lime, and feeding stuffs, can be allowed to continue until the whole interest becomes involved in ruin. Throughout America the consumption of fruit is tenfold greater than with us, and mainly through the facilities and low rates of the railways. It is known that a practical fruit grower, the owner and planter of over sixty acres of the choicer kinds of Pears and Plums on his freehold farm at Slinfold in Sussex, and who has recently made several visits to America, has gathered such information as will greatly assist the Railway Commission on this important question. It is well that facts of the kind should be made public before an official tribunal which will deal with them impartially. Fruit-growers and farmers have borne and suffered long enough.—A FRUIT-GROWER.

GLAZED v. ORDINARY POTS.

I AM very happy to see this subject discussed in a contemporary, though with the exception of the veteran—I might say champion plant-grower of his day, Mr. Thomas Baines—none of the writers can

speak from personal experience of the matter; and as this is a subject that I consider well worthy of being discussed, and having, so far as I know, been the first to make use of glazed pots on an extensive scale and over a period of about twelve years, I would like to offer a few remarks on the subject.

It is now about forty years since I had the opportunity of admiring the beautiful examples of Pelargoniums that the late Mr. Beek of Isleworth used to compete successfully with at the shows in the Botanic Gardens in Regent's Park and elsewhere. These fine plants were grown in neat little slate tubs as close in the grain and as air and moisture proof almost as iron. The plants were beautifully healthy, and, so far as I am aware, Mr. Beek was the first to use these vessels in a systematic way. Cottagers without any reasoning or conviction in the matter, and most probably of necessity, have for generations grown window plants in old cracked teapots, &c. I once judged at a show where the first-prize Fern was presented in a cracked cast-iron porridge or potato pot! So there is no use in discussing who was the first to use glazed or iron vessels for plants, for perhaps it might have been Tubal Cain or some of his contemporaries, and so let them have what credit there is in it.

I do not know of anything connected with plant-growing in pots in which a revolution is more called for than in the description of pot so generally in use. The common flower pot is, to begin with, ugly, especially the English-made one. It is easily broken, and consequently expensive. When water that is soft and of the best description for plants is used it soon gets more ugly still, and dirty into the bargain. It takes very much labour to keep it clean by scrubbing and washing, and every time the process takes place the confervæ or slime is more or less washed on to the surface of the soil, and, in the case of perforated Orchid pots, among the crooks or chareoal and roots; and there it propagates itself and breeds corruption, to say nothing of the breakage of roots in the case of Orchids every time the scrubbing takes place. The roots of a plant must of necessity be subject to chills in it, because when the surface is moist—and it is nearly always so—evaporation is continually going on from its outer surface, and consequently also more water is required for a plant in such a pot.

The common notion that it, the common pot, is better for plants because it is porous and admits air to the roots is simply a popular delusion, like the old saw that "a green yule makes a fat kirkyard," and many others besides. I will not discuss the disadvantage or advantage of air getting at the roots beyond saying that if there were no aperture in a pot besides the usual one, the air would be forced up through it just to the extent that there might be a vacuum; yet this is the chief objection offered to house upon houseful of plants grown in glazed pots here—a knowing shake of the head, and the remark that "Air cannot so well get at the roots." A little of the elements of natural philosophy would dispel that and every other objection that can be urged against glazed pots.

I do not know whether they still exist, but some of the most flourishing Tree Ferns I ever saw were in the Kibble conservatory in the Botanic Gardens, Glasgow, grown in galvanised iron pots or round tubs. This was after I had adopted glazed pots, and it led me to procure the address of the maker of these tubs, and get estimates for various sizes of pots, but I did not feel warranted in going in for them, although not certain that over, say, twenty years the expense would not be in favour of galvanised iron as against common pots if there were no other objections to them. For one thing, the partridge-coloured glazed pot looks far more pleasing. Anyone who will invent a light imperishable—that is, unbreakable pot, at even double or treble the price of ordinary pots, would I am certain confer a benefit on horticulture.

All the stove plants here have for years been grown in glazed pots up to as large sizes as can be made; all the Palms, Ferns, and five-sixths of four large housefuls of Orchids, and there are pots in stock into which the other sixth will be put before many weeks. I have come to look on a common pot for all such plants with a "seunner," to use a scotticism, and will not be satisfied till all our house plants are in them. As to the comparative merits or health of the plants in the two kinds of pots, all I will say is that if I found any plant doing better in the ordinary pot I would not adopt a glazed one. This is not saying that the plants are better or even as good as some grown in common pots, but if they are worse than those of many other cultivators I would not give the dirty old pot the credit of it.

Now as to the expense. The glazed pots cost exactly a fourth more than the common pot, but I have now got them made so that they are much stronger and not so subject to breakage as the old pot, so firm and hard that they ring like a bell. In the end they will come cheaper, especially if the labour of washing and scrubbing is taken into account.

I have this season had glazed suspending pans for such plants as Nepenthes, Dendrobiums, &c.; and they look so much better and

cleaner than the common ware, the evaporation being of course greatly less. Forty of our largest Vandas and a good number of our largest Phalaenopses are in glazed pots, the rest of the latter being in teak baskets, but none in ordinary pots.

Speaking of Orchid pots with holes in their sides, I have come to regard them with disfavour, and am putting those of them in use aside as fast as it can be done. My reasons for so doing are, first the material used for potting is found to decay sooner in them than in close pots, simply because more exposed to the decomposing influence of the air; and secondly because they form a most convenient retreat for a cockroach, a slug, or a woodlouse; and thirdly, because they cost more.—D. THOMSON, *Drumlanrig Gardens*.

FERNS AND THEIR CULTIVATION.

[THE following is the substance of an instructive paper read by Mr. W. Birkenhead of Sale at a recent meeting of the Manchester Horticultural Mutual Improvement Society. For the figures representing the Ferns mentioned we are indebted to Messrs. W. & J. Birkenhead.]

THERE is at once apparent an important and striking difference between Ferns which do not flower and other plants which do; and we might even go further and say that the Fern has no true leaf, and yet its seeming leafiness constitutes most of its beauty. There is, however, this difference between a true leaf and a frond (as the leafy part of a Fern is called)—viz., that the frond produces the spores for reproduction of the species, while true leaves do not; and there is the further difference, that while the leaf of a tree expands in all directions at once, the Fern frond, which has been coiled up much like the spring of a watch, gradually unrolls from the base upward to the apex, the lower part gaining a considerable degree of rigidity while the upper portion is yet soft and still rolled up. So also the pinnae or side branches of the divided fronds partake of the same peculiarity, uncoiling from their junction with the rachis to their extremity. This curious fact leads me to advise people who grow Ferns in windows never to practise turning the plants round with the object of making them symmetrical; for the inevitable consequence is, that while the lower part of an expanding frond has become rigid and unyielding, the upper part, being soft and pliable, will turn towards the light, thus causing the frond to have a twisted or distorted appearance, and as the frond is still hardening this deformity becomes permanent, for turning the plant back to its former position will not bring the frond straight again. A similar difficulty is observed if a growing frond meets with an obstacle in its way and is bent in its growth, and there is no possibility of putting it afterwards into its proper form; hence it is very important to give specimen Ferns plenty of room for development while the fronds are growing, and they will give ample reward for this little attention by their elegance of form, providing, of course, that other necessary conditions of culture are attended to. Of these necessary conditions I will say a few words, and submit that the nearer our culture of Ferns approaches the state in which they flourish in their native habitats the greater will be the success which will attend our efforts, and the more lasting our satisfaction.

One of the first things likely to strike our attention in viewing Ferns in a wild state will be the extreme modesty displayed in their choice of a situation in which to grow, generally in those recesses where the leafy canopy of more gigantic growth shelters their delicate fronds from the fierce rays of the summer sun, and protects them from boisterous winds, or where similar protection is afforded by friendly rocks or sloping banks. These facts will suggest the necessity for providing them with shade from the sun and shelter from the winds; but here in regard to our imitation of Nature let me give a warning against making the gloom too deep, for Ferns cannot grow without light any more than other vegetation. They may not need it quite so intense as many other plants, but light they must have or die.

After giving much attention to the importance of light and its effect upon vegetation as illustrated by several extracts from Dr. Carpenter's works, Mr. Birkenhead continued as follows:—I have all the roofs of my houses washed and thoroughly cleansed by the middle of October, being persuaded that the more light we can get through the glass during winter the more vigorous will be our plants, and to a large extent this will apply in summer also, for even where Ferns are grown I object much to permanent shading where it can be avoided, preferring blinds which can be rolled up immediately the danger of scorching is past, and not allowing them to be put down until the heat of the rising sun makes it unsafe any longer to delay the shade. With this provision, allowing all the light possible to enter the structures, I find those Ferns nearest the glass are the sturdiest, most vigorous, and most shapely plants. Of course there are exceptions to the rule, among which may be mentioned the *Aspleniums*, many of which are benefited by rather more shade, and

the Filmy Ferns, such as *Todea*, *Hymenophyllum*, *Trichomanes*, &c., which require and must have a large amount of shade through the summer months, though even to them I give all the light possible during the dark months of winter.

Another important subject for consideration is the temperature and supply of air for different genera. The Filmy Ferns already mentioned must have an atmosphere heavily charged with moisture, and generally require a house, or frame, or propagating glass to themselves in which to be successfully cultivated, for a current of dry air passing over them for only a short time is often enough to destroy all their beauty. Abundance of moisture in the atmosphere, abundance of water at the roots, and abundant drainage, that the water may escape, are among the necessary requirements of this class of plants, together with rather deep shade in summer. The moisture should be generated by watering the paths and walls rather than by syringing the fronds, though this even is preferable to allowing them to be too dry.

The compost should be very open. It may be composed of peat, strong loam, and stone in equal parts, with or without charcoal, but all in lumps, the fine material being all sifted out and rejected, pieces as large as a walnut and larger being far better than finer compost, except for very small pots. I invariably find the best, healthiest, and strongest roots in the crevices between the pieces of compost, and when fine material has inadvertently been used the

Fig. 16.—*Todea pellucida*.

roots have travelled on the surface and gone down the outside of the pot instead of inside, where, of course, they could get no air. I believe air in the soil to be most necessary, and the quicker the water passes through the soil the quicker the air will follow, and the healthier the roots in that soil will be; and this will apply to nearly all Ferns providing the supply of water is sufficient.

A mistake is often made in the culture of Filmy Ferns by giving too much fire heat, which dries up the moisture from the atmosphere, and inevitably browns the foliage and often destroys it. For most of the species, such as those already mentioned, I would rather subject them to frost than to fire heat. Last winter the Filmies at our place were white with frost, for although there are pipes in the house the heat is never turned on unless the frost is likely to be intense. I have heard of many cases where *Todea superba* and others were covered with frost and ice for weeks together during the severe winters a few years ago, and no harm was done to them. Some of our own plants which were frozen during the same length of time came out of the ordeal without harm. The *Hymenophyllums* and, I believe, the *Todeas*, will grow far better in a close garden frame than in a house in which there is much artificial heat. I have now *Hymenophyllum Wilsoni* and *H. tunbridgense* in a cold frame the perfection of beauty and health, and they have been in that frame since the spring of last year. I hope the knowledge of these facts may become general, so that many persons may enjoy the beauty of foliage, such as that of *Todea superba*, who have hitherto been deterred from attempting the cultivation of Filmy Ferns through fear of disappointment. I must, however, remark that some of the rare and more delicate species of Filmy Ferns, such as clothe the stems of other Ferns and trees in warmer climes, must be provided with artificial heat, but provision must be made for retaining moisture in the atmosphere they grow in, which will perhaps be best accom-

plished by the use of an extra frame or bellglass, so that the dry heat of the pipes or flue cannot possibly come in contact with the exceedingly delicate foliage of such kinds as *Hymenophyllum flexuosum*, *caudiculatum*, and *ciliatum*, *Trichomanes angustatum*, *T. trichodeum*, *T. Luschianum*, *T. pyxidiferum*, and others from tropical countries.

[An example of a beautiful Filmy Fern, *Todea pellucida*, is shown in fig. 16. It is of more slender habit, with looser fronds than *T. superba*, but one of the most elegant of the genus.]

Next to the Filmies in their love of shade and atmospheric moisture come the Aspleniums, some of the Arthropteris, Dictyogramma, Meniscium, Scolopendriums, and most of the Selaginellas, which revel in conditions approaching those in which the Filmies thrive, though being benefited by a little more light and a somewhat greater circulation of air.

Passing from these shade-loving Ferns to the opposite extreme we come to the Pellæas. [Fig. 17 shows a plant of *Pellæa ornithopus brachyptera*, a graceful little Fern] *Cheilanthes*, *Gymnogrammas*,

Fig. 17.—*Pellæa ornithopus brachyptera*.

Ceterach, *Nothochlænas*, and *Woodsias*, Ferns which could hardly exist in the close atmosphere of the *Todea* house, but which, on the other hand, revel in abundance of light and an almost constant circulation of air among their foliage, hence the best situation for such plants is very near the glass on a shelf; but as there are exceptions to most rules, and so also in these general remarks, I may mention *Asplenium Ruta-muraria* and *Trichomanes* as plants fitted for the same situation as the Pellæas and *Woodsias*, remembering, of course, that while these are enumerated with the *Gymnogrammas* as plants requiring extra light and circulation of air, there must still be kept in view the different degrees of heat essential to the different subjects; for while the *Woodsias* will do in a cold house into which the frost may enter, the Pellæas and some *Cheilanthes*, also some of the *Gymnogrammas*, such as *triangularis* and *trifoliata*, in a cool house from which the frost is just excluded, *Gymnogrammas* *Lauchiana*, *chrysophylla*, *peruviana*, &c., must have a stove temperature, still plenty of light near the glass, and a circulation of air created by the hot-water pipes or flue, the driest part of the stove being the best position for the gold and silver species, especially during winter.

Intermediate between the two extreme classes already mentioned—i.e., those requiring shade and atmospheric moisture and those doing better in light and free circulation of air, we have the majority of the members of the family, of which it must suffice to mention a few of the leading genera as representative of hundreds of species and varieties fitted to embellish the stove, the warm greenhouse, the cool greenhouse, the dwelling-room, and the open-air rock garden where shelter is attainable. Such, then, are the species and varieties of the genera *Adiantum*, *Alsophila*, *Anapeltis*, *Athyrium*, *Blechnum*, *Calopteris*, *Cibotium*, *Cyathea*, *Cyrtomium*, *Cystopteris*, *Davallia*, *Dicksonia*, *Diplazium*, *Doodia*, *Gleichenia*, *Lastrea* [see fig. 18 for a good representation of *Lastrea Richardsii multifida*, a useful compact-growing crested Fern], *Leucostegia*, *Lomaria*, *Nephrodium*, *Nephrolepis*, *Osmunda*, *Platyloma*, *Polypodium*, *Polystichum*, *Pteris*, &c., many of which are much more easy to manage than some of the first-mentioned families, and will generally do with a compost of equal parts good loam, leaf soil, and cinders, to which one-half part sand and one-half of charcoal would be a good addition. In the absence of leaf soil good peat may be used for some species, but by no means for *Adiantums*. I am not so much in favour of that generally admired ingredient as some writers seem to be, except for such strong-growing semi-aquatics as the *Osmundas* and *Lastrea thelypteris* (commonly called the Marsh Fern), and a few others.

(To be continued.)

GERMINATION OF PEAS.—As a proof of the mild season and the heat in the ground, Laxton's William I. Pea, sown on January 12th, was plainly showing through the surface on January 31st; thus in

nineteen days from the time of sowing they were showing above ground. I ought to state the seed was sown on a south border that had the protection of a wall some 8 feet in height, the border having been bastard-trenched a few days previous; thus the ground was in first-rate condition for the seed, which was sown as received from the seedsman. The sample was good, and I thought too much dried, but my fears were groundless. All vegetation appears to have made great strides during the past week.—A. J. SANDERS.

VINES BLEEDING.

I AM afraid that if I were to allow "Non-Believer" the cutting and wounding of my Vines as he proposes, it would be done with "malice aforethought" as far as the Vines are concerned; and as they are accustomed to be ministered to only by loving hands, they might find out the difference. On looking over what I have written I cannot find anything which can be construed in the way your correspondent puts it, but if others think there are passages which can be so interpreted I am glad he has called attention to them. What I have endeavoured to say is that the bleeding when it takes place is little more than an emission of water, and that the stores of food are not materially exhausted thereby. I have had some Vines bleed as I thought very seriously, while others of the same variety, apparently in the same state of vigorous health and treated exactly the same, have not bled; and yet after growth had started those which had bled profusely flourished as well as those which had not bled at all. I cannot give a reason why some should bleed and others should not, neither can I say why bleeding sometimes comes on, ceases suddenly, and then comes on again. I have thought sometimes the weather or the temperature made the difference, but on following up any clue which I thought I had got hold of I have not been able to go far without experiencing a check, and there is still much that is mysterious about the matter.

The sentence which your correspondent alludes to is probably the following, and is from the Journal of November 22nd, at page 438:—"The liquid which comes from a Vine stem when it is pruned too late in the season is, I believe, very little, if anything, more than water; it is perfectly tasteless, and beyond keeping the wound open probably does no harm." I thought it was sufficiently plain in this sentence that Vines can be pruned too late, and also that cutting and wounding was an evil—a necessary one it may be—not to be repeated for mere amusement.

Another sentence which bears on the subject is from the Journal of December 20th, at page 529, where, after citing an extract from Prantl's "Text Book of Botany," describing the movements of water in plants, I say that "Prantl's theory agrees with what has been guessed at by several practical gardeners, and recorded within the last few years in this Journal—namely, that little or no harm happens from the bleeding of a healthy Vine, as there is little or nothing besides water exuded; and there is, or ought to be, always an ample supply at the command of the

Fig. 18.—*Lastrea Richardsii multifida*.

plant to replace that which is so lost." Here I thought it was sufficiently clear that I was giving other people's opinions and theories, but if I am not clear I wish now to repeat what I have often said in this Journal, that late pruning is decidedly injurious to any plant. I have always made a practice of completing the pruning, both indoors and out, as far as I could, of all fruit-bearing plants before Christmas, including even the Peach and the Fig, for all plants, whether they bleed visibly or not, are decidedly injured by amputations performed just before growth commences.

"Dugald's" letter on "Vine Economy" is interesting, but not convincing. Supposing we grant all he states to be correct, and some of it I am willing to grant, there yet remains the fact that Vines start making leaf-growth first, and other plants, as far as I know, start root-growth

either before or simultaneously with top-growth. It would be interesting to know, as far as can be discovered by the microscope, what proportion of stored food the Vine has in winter compared with other fruit-bearing plants—say, the Plum for instance, which starts root-growth soon after, or even before Christmas, in the southern counties when the weather is not severe.—WM. TAYLOR.

PEAS IN 1883.

It is seldom we experience so good and prolonged a Pea season as that of 1883. We commenced to pick in quantity about the middle of May, and were never without Peas till nearly the end of November. It is true we took extra pains with both the earliest and latest crops, the seed for the former being sown in boxes and the seedlings transplanted and carefully sheltered from cold winds and frosts, while the latest sowings were made in the highest situated quarter of the garden where the earliest frosts are least destructive, but they well repaid for the trouble.

For the very earliest pickings American Wonder is the best, being well adapted for either frames or for sowing or planting at the base of sunny walls. The quality of this extra dwarf wrinkled Marrow is first-class, and each season I have either this or the still more dwarf Minimum. Complaints have been made of the quality of the earliest round-seeded Peas grown to succeed them. I hope in time we may dispense with any round-seeded varieties, but up till now no wrinkled Marrow I have tried is quite early enough. Laxton's Earliest of All was again the best early variety, and was closely followed by Veitch's Extra Early, this white round-seeded selection being the more robust of the two. William I. was fully a week later than the last-mentioned, and as usual proved very serviceable. A large-seeded wrinkled Marrow received from Mr. E. Tredgett, Cambridge, formed a good succession to William I., and apparently possesses a stronger constitution than most of the earliest section. Magnet, a dwarf second early variety, proved useless here, but might suit gardens where space is limited and stakes scarce.

Telephone, which I prefer to Telegraph on account of its superior quality, is still the best second early Pea; and as a substitute for the former in smaller gardens I would recommend Stratagem and Pride of the Market, also of moderate height and very sturdy, being, like Telegraph, of a better colour but less sweet. To form a succession to Telephone we still prefer Criterion, while those preferring Peas of the Champion of England class to the better-coloured Ne Plus Ultra type, in which Criterion must be included, should grow Huntingdonian. Both are heavy croppers, fill their pods well, the peas being of the best quality. Dr. McLean is good for a small garden, and so also are Marvel and Gladiator. The latter was first distributed last season, and I should be glad of other growers' experience with it. With me it cropped heavily, and the long pods filled well, but the quality was poor. Evolution branched remarkably, was very prolific, and the long handsome pods were closely filled with not oversweet peas. Another novelty, Sturdy (Veitch), much resembles it in habit, but is much later, and the pods are smaller, but are closely filled with sweet peas. A third branching variety was received from Messrs. Sutton & Sons for trial, and this when distributed will be found to be one of the best white wrinkled varieties we have. These branching varieties, among which Walker's Perpetual must be included, are great acquisitions, especially for small gardens. The last-mentioned will in our case take the place of Veitch's Perfection, which it resembles in some respects.

I do not consider Culverwell's Giant Marrow particularly valuable, as, unless it receives special treatment, the pods are not very large, and I find it much subject to mildew. The pods fill well, and the peas are large and sweet. As an exhibition variety I consider the better-coloured Evolution superior to it, and I have observed that judges are paying more attention to colour than of old. Reading Giant is a good main-crop sort; the habit, colour, and size of pod and peas as well as the quality being alike satisfactory. Ne Plus Ultra is too well known to need any recommendation from me, as it is undoubtedly the best late tall sort we have. Suttons' Latest of All was again remarkably good for late crops and does not require tall stakes. Doubtless there are other varieties besides those enumerated above which are worth growing, but I am not acquainted with them.—W. IGGULDEN.

ROSES NIPHETOS AND SAFRANO—SCENTLESS FLOWERS.

I AM somewhat surprised that the Tea Rose Niphetos should be placed in the foremost rank, and that it is considered by some as likely to become at no distant date the Rose of the future for winter forcing. What merits does it possess when forced inside? Does it bloom with greater freedom than all other varieties? I cannot see any qualities to justify its being accorded such prominence, unless the pure white blooms are alone the merit by which it has gained such a high position in popular estimation. It is by no means the most prolific-blooming Rose that can be grown

when forced during the winter. The old apricot-coloured Safrano must stand far ahead of it for winter forcing; in fact, it is the most continuous flowering Rose that can be grown for flowering either winter or summer either in a pot or planted out, but it is for the former that it is most valuable. During that period it will produce double the buds, or nearly so, that Niphetos will; but only in the bud state is it any use, for it does not possess sufficient petals for the exhibition table. Probably on this account Niphetos is placed before it. But for winter forcing varieties cannot be judged by the exhibitor's estimate or standard, for even Niphetos, which during the summer attains such size and beauty, is equal only during winter in the size of its buds to Safrano. The last is, I will readily admit, a disappointing Rose when fully expanded, and but little superior to those of the common Briar, except that it is larger; but in the bud state it is a gem, and possesses the advantage that few other Roses have of developing after being cut and placed in water. Even if cut in a small state it will do this.

Again, the buds of Safrano possess a most delicious fragrance, while the popular Niphetos possesses only a very light fragrance that is almost imperceptible. Why a scentless Rose should be elevated to the foremost position for winter I cannot imagine. I give preference to several varieties before it. If it possessed the fragrance of Safrano it would be accorded the second position, for it surpasses that variety only in the colour of its flowers. I think these scentless Roses, whether Teas or Hybrid Perpetuals, cannot be too strongly condemned, and yet they are becoming more general, and many of them for form and beauty rank high amongst exhibition varieties. If we look at the gigantic blooms of Capitaine Christy, Baronne de Rothschild, Mabel Morrison, Comtesse d'Oxford, Magna Charta, and many others, they are no more beautiful or desirable than Camellias, which are more readily produced during the winter and spring. The latter possess qualities that should place them in higher estimation than scentless Roses, but such is not the case. I most decidedly prefer to large scentless blooms, however faultless their form may be, buds of the old Cabbage, common Moss, or China Roses, all of which would be ignored by the lover of Roses for exhibition only.—W. BARDNEY.

SPECIAL SOCIETIES.

IN reply to Mr. Douglas on page 88 I do not feel at liberty to publicly name Auricula growers who sell their seed and plants, as some of them are not independent amateurs. Florists have generally on hand a stock of good, bad, and indifferent plants, and they very seldom object to dispose of these to the highest bidder—trading upon their reputation to "turn an honest penny." I have, however, no objection to give the name of one notable "florist" and Auricula grower to the Editor privately, and I leave it to his discretion to give it to Mr. Douglas in the same way, who sells his seeds or seedlings regularly. Looking at a large stock of these one day I asked the nurseryman if they were florists' varieties, and his reply was, "Well, we buy all so-and-so's spare stock and pay a good price for them, and if they are not florists' varieties they ought to be." Does Mr. Douglas mean to deny that florists do not "trade in their specialities?" I have a list of named "florists'" flowers before me now, compiled by one who is intimately acquainted with all the Auricula growers in the kingdom, who reports their doings, exhibitions, &c., very frequently; and he most assuredly does not offer his plants or seeds for nothing, nor does he get them for nothing from those who cater for him. No one finds fault with florists having an "eye to business," only I wanted to show that the "old fogies" are not exactly the guileless philanthropists your correspondent would have us believe.—BORDER FLOWER.

WONDERFUL are Mr. Douglas's discoveries! His latest, perhaps his most wonderful, that the National Rose Society must drop its title of National because none but members can exhibit at its shows. He had better write to the National Club or the National Liberal Club to say that they must change their title because none but members can use their privileges. National simply means general, public; and all it implies is that anyone may belong to an institution using the name on certain conditions. To the National Rose Society, hitherto by payment of an entrance fee of 5s., now by simply doubling that and thus becoming members and entitled to other advantages besides that of being able to exhibit.—D.

I REALLY had no intention of hurting the feelings of Mr. Rudd or Miss Woodhead either, and I am quite astonished that "D., Deal," accuses me of doing so. I stated plainly that there was some mistake which "D., Deal," can doubtless set right. It was stated at the Show in question that Mr. Rudd had offered 1000 plants of Auriculas at a price. There is no other amateur known to me that could do so. As it seems "D., Deal," was the first to introduce this personal matter, I look to him to say who the amateur was.—J. DOUGLAS.

NOTES FROM A SUBURBAN GARDEN.

Lasiandra macrantha floribunda.—Those who grow this charming Melastomad in the form of small plants in pots only, can form no idea of the size it will attain when planted out in generous soil and encouraged to grow freely in a somewhat moist and intermediate temperature—a fernery for instance. A very fine example, affording an illustration of the preceding remarks, has flourished and flowered

vigorously for many years in a large fernery under my charge. Its principal shoots were trained up one of the supports of the roof, thence along one of the cross beams; and now the drooping mass of lateral growth laden with its lovely purple blooms hang gracefully down from the beam, thus affording in contrast with the surrounding Ferns a most pleasing picture, especially as this charming plant is almost constantly in flower. A great point in its favour, too, is its comparative immunity from the ravages of insects, the only insect we have found to infest it being mealy bug, and this may be very easily kept in check, or, what is more preferable, exterminated by paying diligent attention to the matter. Such a beautiful climber deserves to be more generally grown than it now is.

Justicia flavicoma.—This useful old inhabitant of our plant stoves is not grown so extensively as it deserves to be. Its bright yellow flowers are very cheerful, and useful, too, for cutting during the dull period of the year. Healthy well-grown plants will be found very effective for the decoration of rooms and the plant stoves at all times, but more especially during winter when flowering plants are scarce. Cuttings taken in spring, inserted in heat and grown on during the summer, will make useful plants by October, when they will commence flowering and continue to do so for a long time.

Cibotium Schiedei.—A truly noble Fern is this when well grown, and plenty of space is at command to enable it to fully develop its large elegant fronds. To enable it to do so it requires a large structure, and if possible to be planted out. To see it to the best advantage, too, the fernery should have its interior arranged in a series of rock banks and beds. These should be constructed or formed in as tasteful and informal a manner as possible. By a judicious employment of large boulder stones in certain portions of the house, according to the effect required, suitable positions for these noble Ferns may be found—that is, if intelligently done. It is impossible in these brief notes to enter fully into the arrangement and design of such a structure as is best adapted to the growth and development of Ferns. We may, however, state that if this species be given a commanding position in such a structure, and can be planted out, it will speedily become an object of admiration.

Onions.—So many varieties, with their endless “improved” forms, are to be found in seedsmen’s catalogues that it is a task of no small difficulty as well as a source of bewilderment to beginners in gardening to select the really best varieties capable of producing good bulbs in quantity and quality. After a careful trial last season of several varieties we found such as James’ Long-keeping a first-rate Onion for keeping, Bedfordshire Champion and Sutton’s Improved Reading (this is a superior form of the latter variety) to be the best varieties for main crop. As a small Onion useful for garnishing and pickling and turning in early for use we recommend The Queen, one of the Silver-skin type. The Paris Silver-skin is a useful variety for drawing in a young state for soups. Giant Lemon Rocca as a winter sort is doing well with us.

Strawberry Triomphe de Paris.—Have any readers of the Journal grown this variety for forcing? If so, has it been found a good variety for that purpose?—SUBURBANIST.

THE Committee of the KINGSTON CHRYSANTHEMUM SOCIETY met on Wednesday the 30th ult., and decided to offer another 25-guinea challenge cup, with money prizes of £5, £4, £3, and £2 to go with it. There are also prizes of 80s., 40s., 30s., and 20s. for twenty-four incurved cut blooms, and likewise the same amounts in a corresponding class for Japanese blooms.

— EAST LOTHIAN STOCKS.—Mr. Thomson writes to say that Mr. Muir is wrong in crediting him with bringing out these Stocks, and that it was Mr. James Campbell (now in a situation near Melrose) when gardener at Traprain who selected them and grew them for years, in common with several other East Lothian gardeners, before Mr. Thomson grew them, and who claims no more credit for them than having written in their praise after having grown them extensively, and desires to accord honour to whom honour is due.

— THE schedule of the NEWCASTLE-UPON-TYNE HORTICULTURAL AND BOTANICAL SOCIETY announces that the spring Exhibition will be held in the Town Hall and Corn Exchange on April 23rd and 24th,

when £138 will be offered in prizes for bulbs and miscellaneous forced plants and flowers. The summer Exhibition is fixed for July 23rd, 24th, and 25th, the Leazes Park being the site selected. A total of £302 will be offered in prize money for plants, flowers, and fruits, some of the individual prizes being of considerable amount.

— ONLY about 57,000 barrels of AMERICAN APPLES have been exported to Great Britain this season, of which nearly 70 per cent. has been shipped from New York, 13 per cent. from Boston, and 17 per cent. from Montreal. Nearly 300,000 barrels were shipped in 1882. This season Liverpool has taken the largest proportion, Glasgow next, and then London and other smaller ports. In 1882 Liverpool imported nearly 200,000 barrels of American Apples.

— MR. WILLIAM GREGORY, late nurseryman of Cirencester, died at Harlesden, Middlesex, on the 29th January, aged eighty-five. Mr. Gregory succeeded his father, who was founder of that business now so energetically carried on by his kinsmen, Messrs. John Jefferies & Sons of Cirencester. Forty years ago Mr. Gregory took an active part in all the leading horticultural movements of the period, and was one of the founders of the Gardeners’ Royal Benevolent Institution.

— THE SUTTON AMATEUR ROSE SOCIETY’S schedule, which is just issued, gives the date of the Show for the present year as July 4th, the site selected being the Sutton Public Hall. The total amount of prize money offered is £82 in twenty-four classes, a number of special prizes being contributed by supporters of this energetic Society. The National Rose Society’s silver medal will be given for the best Tea and Noisette, and the bronze medal of the best Rose in certain classes. A ladies’ challenge cup is offered for six blooms, single trusses, the cup to be held by the winner for the year, and if won by the same member in two consecutive years it becomes his property. This Society appears to be extremely well supported, for although only the third year of its existence, they have the substantial balance of £41 10s. 3d. in their favour.

— AT the recent meeting of the ROYAL BOTANIC SOCIETY, Regent’s Park, a further collection of tropical fruits, seeds, &c., collected by Lady Brassey during her recent voyage to the West Indies, was placed upon the table and explained to the Fellows present by Professor Bentley, Dr. Prior, and the Secretary, Mr. Sowerby.

— “R. I. L.” writes that “IRIS STYLOSA, as ‘M. S.’ suggests should be grown in all gardens. During the mild weather of the past winter it has constantly been flowering out of doors, but that cannot happen with much advantage during the most usual weather of its season of flowering, and therefore, as in the Cambridge Botanic Garden, it should be grown in pots for the greenhouse. It submits well to pot culture, and the most lovely flowers have almost constantly been in perfection for a number of weeks. Who has seen Iris Robinsoniana in flower? Surely that comparison has been made from a figure.”

— A CORRESPONDENT regards GARRYA ELLIPTICA “as one of the most valuable of hardy evergreen shrubs. Though it was injured by the late severe winters, it has now quite recovered its appearance, and the male catkins, which give such a decided individuality, are now in perfection. It is native of Mexico and California, and Loudon says that in America it reaches a height of 3 to 4 feet; in Britain, however, it attains to 8 or 10 feet. The female plant is extremely uncommon, though by layers and cuttings it should easily be propagated. The male, fortunately, is the handsomest, and we have pendulous necklace-like catkins before us nearly 7 inches long. These are extremely graceful.”

— A CORRESPONDENT, “H. T. H.,” desires to know if any reader of the Journal can tell him where he can buy a VINEGAR PLANT. He has fifty gallons of cider that would make excellent vinegar if he could obtain the plant in question.

— MR. J. SAUNDERSON, The Gardens, Bodnant Hall, Eglwysbach, Denbighshire, writes:—“Having read your correspondent, C. H. Stephens’ article on POINSETTIA CULTIVATION, I doubt whether such treatment would answer in this part, or even anywhere far north of London. We find them succeed best in an intermediate temperature. I have forwarded you a sample head, cut from a plant 30 inches high with leaves to the pot rim. We have them from 10 inches to 3 feet high.” Accompanying this note was a head of Poinsettia bracts and flowers 18 inches in diameter, with six branches and individual bracts 10 inches long, 2½ inches broad, and of extremely rich colour. Such plants as Mr. Saunderson grows must be extremely showy.

— ONE of the best of a fine genus is *APHELANDRA ROEZHII*, and so useful that it deserves mention, though well known, probably, as one of the best of stove plants. There are few plants which flower so well as small specimens, and it can be cut back and flowered so readily upon short branches that it is of great value now that decorative plants of small size are in demand. At Gunnersbury we remember having seen some very fine specimens. It is easily raised from seeds, and is grown also from cuttings. Like the other species, it delights in rich soil with good heat and moisture. As may be remembered, this species is characterised by broad, silvery, deflexed leaves, above which stand erect the close spikes of brilliant orange-crimson flowers.

— CAULIFLOWERS imported in casks from Germany have been recently on sale in New York city. Cabbages have become a common import there, and are absolutely sold cheaper coming from Germany than from Long Island. Fresh Cauliflowers will be imported in May and sold at good profits.

— It is announced that PROFESSOR FLOWER has been appointed to the post of Superintendent of the Natural History Department of the British Museum, rendered vacant by the resignation of Sir Richard Owen recently noted.

— DISASTROUS EFFECTS OF THE LATE GALES.—It is stated that not less than 20,000 trees have been blown down on the Countess of Stair's estate, near Ayr; 100,000 in the one case and 20,000 in the other on the Marquis of Ailsa's estates at Mochrum Hill and Culzean Castle. We are also informed that 150,000 trees have been blown down in the Duke of Buccleuch's forests on the Drumlanrig estate.

— AN American paper states that "A new Mignonette, *RESEDA ODORATA MACHÉ*, is hailed with pleasure by those who understand the usefulness of this flower and its standard popularity. It is entirely distinct from all other varieties known. Its foliage is bushy and very dark green. Its habit is dwarf; it is very vigorous, throwing up numerous flower stalks, terminated by massive spikes of deliciously scented red flowers."

— MISS ELEANOR A. ORMEROD has issued an interesting little work, entitled "A GUIDE TO METHODS OF INSECT LIFE" (London: Simpkin, Marshall & Co.). It comprises ten lectures, which were written at the request of the Institute of Agriculture as a compendium of information on the habits and means of destroying insects injurious to farm and garden crops. One hundred and sixty-seven pages are devoted to the subject, which is fully treated and abundantly illustrated with representations of all the principal pests, the several stages being also shown in most cases. A useful glossary of entomological terms and a good index render the work still more serviceable.

— "W. J. H." writes in reference to PEDIGREE ROSES:—"In your number of January 24th, 'D., Deal,' in his review of horticulture, speaking of the Rose, admits the success of Mr. Bennett's hybridising, but objects to the term 'pedigree' as applied to them. If he has not already given his reasons, may I ask why? If Mr. Bennett carefully crosses his Roses and keeps a correct memorandum of the same, why should he not so call them if he thinks fit? In regard to Her Majesty, do I understand that he doubts the pedigree, or that he is not prepared to admit that it is any improvement on the older varieties? If the former, why? If the latter, I consider that according to the exhibition test of the National Rose Society it has proved itself a decided advance on any other Rose. At the Society's Exhibition in London it was awarded their gold medal for the best seedling, and the first prize for the best twelve blooms in the Show both there and at their Sheffield meeting; and although the Roses awarded the second prize were decidedly good, there was, according to the opinion of more than one present, room for several between them."

— THE *St. James's Gazette* recently published an interesting article upon NARCISSI CULTURE in the SCILLY ISLANDS, from which we extract the following:—"Several years ago it occurred to the late Mr. Augustus Smith—whose intelligent interest in horticulture is well known, and has left a permanent monument of itself in the Abbey Gardens at Tresco—to test the capacity of the island soil for producing the Narcissus. The plant was introduced more or less widely—scarcely with much hope of profit at first. It is probably not more than six years ago when the first consignments of Narcissi from the Cassiterides found their way to Covent Garden. Now some of the large growers at

Scilly have as many as 200,000 bulbs, each supporting on a long stem the beautiful flower so much valued for house and church decoration. What this may mean in the way of prosperity can be roughly estimated when we learn that the Narcissus has sold for 1s. 6d. per bunch of a dozen in the closing days of December. Also, it is to be noted that the bulbs multiply rapidly; they double, treble, and even at times quintuple in one year. As a climax to all this good fortune, there is no reason to suppose that Scilly need fear competition of a dangerous sort. The Narcissus farm at Rocky Hill is well worth a visit. The land devoted to the flower is fenced with deep, thick, dark green hedges of *Escallonia*, all trimly cut, which form also a pleasant contrast to the bright tender green of the Narcissus leaf. There the plant grows luxuriantly in long rows of beds, and where the shelter is most complete the stalks are sometimes nearly a yard in length. Nothing is much pleasanter for those who care for flower-gathering than to spend an hour or two plucking the fresh crisp stalks. They are set side by side in deep round gathering-baskets. Thus collected, they are conveyed to the farmhouse, sorted and tied in bunches. A dozen stalks form a bunch, and some little experience is necessary to attain perfection in the art of tying them up satisfactorily. Fifty or sixty or seventy bunches make up each basket, which is then ready for forwarding to Covent Garden."

— PROVINCIAL correspondents writing from Devonshire and Cornwall in reference to the MILDNESS OF THE WINTER, state that Strawberries have been picked both by hedgerow and in gardens, while Blackberry bushes with both fruit and blossom thereon may be seen. The cottage gardens, many of them, are already bright with early spring flowers. The following wild plants have also been seen in bloom:—*Primula vulgaris*, *Stellaria media*, *Ranunculus bulbosus*, *Ranunculus Ficaria*, *Rubus fruticosus*, *Fragaria vesca*, *Potentilla fragariastrum*, *Lychnis diurna*, *Bellis perennis*, *Lamium purpureum*, and *Vicia sepium*.

— THE fifth annual general meeting of the LIVERPOOL HORTICULTURAL ASSOCIATION was held in the Free Library recently, Mr. Thomas White, Vice-Chairman, presiding. The reading of the report of the work of the past year—the most successful of the Association—elicited from the members warm approval, and satisfaction was expressed with the Committee and officers for their services. The election of Patrons, Honorary President, and Vice-Presidents was then proceeded with. His Worship, the Mayor (Mr. Thomas Holder) was unanimously elected Honorary President, Mr. Fletcher Rogers being re-elected Honorary Treasurer. Mr. William Minshall, Sub-Treasurer, and Mr. Joseph Gore, Secretary, were unanimously re-elected. A vote of thanks was given to the retiring officers and Committee for their past services, their unremitting energy having placed the Association in its present favourable position. The rules of the Society, having been revised by a Sub-Committee composed of Messrs. A. R. Cox, R. G. Waterman, and E. Bridge, were passed with slight alterations, two Auditors having been appointed. Several members expressed a favourable opinion about the forming of a reserve fund, and it was agreed that the Committee take this matter into their consideration at an early meeting. A vote of thanks to Mr. T. White for presiding terminated the proceedings.

— G. T. GWILLIAM, Esq., Fellow of the Royal Meteorological Society, refers in the *Daily News* as follows to the MILD WEATHER:—"The mean temperature of the air here last month was 44°, being 5·6° above the average. It was the warmest January since 1834, and the only instances recorded of a higher temperature in this month were in January, 1796, mean temperature 45·3°; January, 1834, mean temperature 44·4°. The continuous mild weather has been very remarkable. Since December 8th, 1883, the 'shade temperature' here has not once fallen below 32°. During the same period of 1879–80 it fell below 32° on forty nights."

— DURING the recent gale one of the most noted trees in Sherwood Forest fell a prey to the wind's violence. It was known as the "MAJOR OAK," and was situated near Edwinstowe. The tree, a grand old Oak, had a girth of 29 feet, and "the circumference of the outspread tree at the utmost extent of its branches was 240 feet." It was at one time called the Cockspen Tree, because its interior was used formerly as a hen-roost. Latterly many pic-nic parties have gathered in the hollowed-out trunk, and in a history of Worksop the following reference is made to the tree:—"Seven persons at once have been known to partake a meal in it; while no doubt with a little contrivance it might have accommodated more." Notwithstanding its internal

decay, the old Oak (which had existed for more than seven centuries) was one of the noblest trees in the kingdom.

— THE age and size of large trees is commonly over-estimated. The largest known Red-wood of California is 366 feet high, and all higher measurements which have been given are erroneous or guessed at. They are probably not nearly so old as usually represented.

— THE remarkable Aroid *GODWINIA GIGAS* is now fast developing an immense spathe in Mr. William Bull's nurseries, King's Road, Chelsea. This extremely rare plant was discovered by the late Dr. Seemann when collecting for Mr. Bull on the Chontale mountains, Nicaragua. This specimen flowered once before in this country, and the spathe then measured 1 foot 11 inches in length, and 1 foot 8 inches in width. The spathe in its present state of development is not so large as that, being 18 inches long, and 9 or 10 inches broad when open. It is of a peculiar claret-purple colour, except at the base, where it is yellowish, the spadix being short and of a dark hue. The large solitary leaf was 9 or 10 feet high last summer, and from the lower portion of the remaining leafstalk is produced the spathe, which is borne upon a stem about a foot long, curiously spotted and striped with grey on a greenish ground. It is strange that after the lapse of ten years the same plant should again produce flowers.

— MR. J. H. KRELAGE of Haarlem has sent us a paper by Dr. Wakkers, the object of which is to show the impossibility of communicating the *PHYLLOXERA* by the agency of bulbs and tubers. In our opinion there is not the remotest danger of anything of the kind occurring, nor is there any probability of the pest being introduced by other plants than the Vine, unless these are actually grown in vineyards, and in that case it is possible that the eggs of insects might be conveyed in the soil. No satisfactory proof that we are aware of has been furnished either by experiments in this or any other country that the much-dreaded insect will live on any other roots than those of the Vine. We have heard fears expressed that the insect may be introduced with Lilacs for forcing, but the best Lilacs are grown far distant from the phylloxera districts, and, moreover, we are told on good authority that they are grown in pots; but at any rate there is no phylloxera in the bulb farms of Holland, and obviously there can be absolutely no danger of introducing the pest from where it does not exist. We are, however, informed that it is the custom in some continental nurseries to grow the Lilacs and Roses in rows between the rows of Vines, and it is very desirable that such a practice should be discouraged, as the danger of introducing the eggs on the roots in those cases is a contingency not to be overlooked.

VEGETABLES FOR HEAVY SOILS.

NOTHING influences the growth and the quality of vegetables more than the nature of the soil in which they are grown. Some varieties are more easily influenced in this respect than others; this being the case, a knowledge of the varieties which succeed best on light or heavy soils is all-important to those who have to cultivate them. I propose to name a few varieties which we have found can always be depended upon to give good crops on our heavy soil.

Potatoes—first crop, Rivers' or Myatt's Ashleaf; second crop, Covent Garden Perfection. This I consider the perfection of a Potato, and it is always good with us. Late crop—Champion and Reading Hero, the latter is the best. Peas.—First crop, William I; second crop, Telephone; on this variety I chiefly depend for the summer supply, and it never fails to give peas of excellent quality and plenty of them. Late crops—none does so well here as Ne Plus Ultra. These are all tall varieties, which I always grow in preference to the dwarf ones, but in small gardens where space and sticks are an object, American Wonder, Stratagem, and Omega should be substituted for the above, and will not fail to produce excellent crops.

There is no need to particularise any variety of Cauliflower or Broccoli, as they all delight in soil of a heavy nature. Cabbage—Carters' Early Heartwell gives the most satisfactory results. Chou de Burghley I hardly dare venture an opinion upon yet; mine are rough this season, and the amount of cooking required to make them tender takes out all the colour and flavour, but I intend giving it another trial in hopes of better results. Of Brussels Sprouts I have not grown any variety to please me yet; but I saw last year in the kitchen gardens at Longleat a quarter the counterpart of which I wished I had at home. The variety was Paragon, obtained from Messrs. Veitch & Sons, and which I intend trying myself this year.

Carrots are difficult to grow satisfactorily on heavy soils. The Short Horn varieties do best, and James's Intermediate is good for

winter use, but it should not be sown until the first week in May, or half the crop will split and be spoiled.

Celery, with the exception of a few rows of White, for early use, from a stock of my own, I grow Carters' Incomparable Crimson, it is more hardy than Major Clarke's and remains solid to the last.

Lettuces for summer use, a good strain of Alexandria White Cos. We generally lose a good part of our Lettuces in winter through damp. Hick's Hardy I can do nothing with, and Brown Cos sometimes goes off entirely if we have much wet weather. The variety that stands best is comparatively new, called Hardy's Northern King, sent out by Messrs. Carter & Co. Of Cabbage varieties, Hammer-smith for winter, Paris Market for foreing. Endive—Broad-leaved Batavian.

Onions—White Spanish and James's Keeping; the latter keeps sound the longest, but is not so good in flavour as White Spanish. For autumn sowing—Queen, Giant Zittau, and Red Italian.

In sowing the seeds, also in transplanting young plants, use plenty of burnt refuse and old potting soil; more especially is this beneficial to Onions and Carrots, it gives them a good start, and puts their insect enemies at defiance.—ARTHUR BARKER, *Hindlip Gardens*.

HARDY PLANTS IN BLOOM IN JANUARY.

THE first month of the year is usually a dull one outdoors, but owing to the mild genial weather many plants that do not usually bloom till March and April are now showing their flowers. Some of the plants enumerated below are very beautiful, notably *Eranthis hyemalis* (Winter Aconite); thousands of them about the shrubberies and under trees look like sheets of gold. It reproduces itself freely from seed. Snowdrops are clean and good, and I have never seen *Jasminum nudiflorum* on the walls better than this year. *Narcissus Bulbocodium* (Hoop-petticoat Narciss) planted in the grass seems quite at home, and opened its flowers on the 20th of January, the earliest period I ever remember to have seen it; also *Leucojum vernum* (Snowflake) in clumps near it. Another plant that has bloomed most freely all through the autumn and still looks well is *Veronica Blue Gem*. This is a plant usually grown in pots for decoration, and very good for that purpose it is; but two little plants were turned out of pots last spring and planted in the rock garden, where they grew freely all the summer, and are now miniature bushes 2 feet high and as much across, and every shoot blooming well. This *Veronica* withstood 16° of frost last winter planted in the kitchen garden, and bloomed well the summer following. It is well worth growing for autumn decoration for a conservatory, and to flower it well must be stood in the full sunshine outdoors, with plenty of water as required, and pinching the shoots once or twice to make bushy plants.

Some clumps of *Geum coccineum* have produced flowers every month since last June, likewise *Erodium Manescavi*. These two are very useful for cutting purposes. *Helleborus niger* has been grand this last month, also *H. atro-rubens*. *H. foetidus*, with its green flowers, is rather a rank grower, and is more suitable for planting in the background. It seems to thrive in the shade under trees. Some Roman Hyacinths were planted in the rockery in October and are now showing colour. How they will succeed in a second year is questionable, but I shall leave them where they are to try. I have never known much good to be done with the forced bulbs after once flowering. Many times have I planted them in the grass and shrubberies with *Crocus*, *Narcissi*, *Tulips*, *Scillas*, and other bulbs; and although the latter have invariably come up and flowered all right, the Roman Hyacinths did no good. Possibly there may be some special treatment required for them after flowering, and if any of your numerous correspondents have succeeded in flowering them well a second time their practice would be worth recording, as there is no bulbous plant more useful to the gardener, and none more cheerful in rooms at midwinter. The following plants are now flowering here:—

Myosotis dissitiflora.

Geum coccineum.

Veronica rupestris.

" *Blue Gem*.

Violets, single and double.

Primroses, " "

Wallflowers, red and yellow.

Roman Hyacinths, white.

Erodium Manescavi.

Erica carnea.

Saxifraga ceratophylla.

Scilla siberica.

Snowdrops.

Polyanthus.

Helleborus niger.

" *atro-rubens*.

" *foetidus*.

Pansies in variety.

Daisies, double, in variety.

Berberis Darwinii.

Aubrietia purpurea.

Arabis alba.

Omphalodes verna.

Hepatica triloba corulea.

" *rubra plena*.

Eranthis hyemalis.

Pulmonaria officinalis.

Vinca minor.

Anemone coronaria.

Narcissus bulbocodium.

Leucojum vernum.

Crocus, yellow.

Scabious, dwarf.

Stock, Intermediate.

Jasminum nudiflorum.

—A. HARDING, *Orton Hall Gardens, Peterborough*.

COMMERCIAL ENTERPRISE IN CALIFORNIA.

OF recent years the interesting region on the extreme west side of the United States has attracted much attention as a field for agriculturists, and the facilities afforded to emigrants from this and other countries have caused a great influx of settlers. A fine climate, a great diversity of

fertile soils, and cheap land have enabled many small capitalists with a knowledge of farming to establish themselves in the new country on a large scale. Extensive orchards of Apple trees, Oranges, and Lemons, vineyards, Hop gardens, and vegetable farms are gradually spreading over the country, while in addition to these forms of industry bee-culture

fornian products on view, comprising samples of the different local varieties of grain, Apples, and miscellaneous fruits, together with sensational Vegetable Marrows and Pumpkins. A series of elaborately illustrated guides to the country are also issued from the same agency, giving full particulars respecting the climate, land, most profitable crops, &c.—information of great value to intending emigrants.

The scenery of some portions of California is well known to be unexcelled in variety and striking beauty, the celebrated Yosemite Valley especially having afforded a theme for many writers and travellers. The two views accompanying these notes will convey some idea of the principal features of the valley. The Sentinel Rock shown to the right of the general view of the valley (fig. 19) is a mass of perpendicular granite tapering into a peak 3043 feet above the level; but this is surpassed by El Capitan, which rises to 3300 feet; the Cathedral Rock and Spires, about 3000 feet; and the Three Brothers, 3830 feet high, are the principal elevations, which rising direct from the level of the valley impart an extraordinary appearance to the scenery. The Yosemite Falls (fig. 20) is another extraordinary feature. They are opposite the Sentinel Rock, and from March till July are exceedingly beautiful. The total height of the fall is 2526 feet in three sections—first a perpendicular descent of 1500 feet, then 600 feet of cataracts, and a final leap of 400 feet. "Professor Whitney concludes a description of the Yosemite Falls as follows:—'As the various portions of the falls are nearly in one vertical plane the effect of the whole is nearly as grand, and perhaps even more picturesque, than it would be if the descent were made in one leap from the top of the cliff to the level of the valley. Nor is the grandeur or beauty of the fall perceptibly diminished by even a very considerable diminution of the quantity of water from its highest stage. One of the most striking features of the Yosemite Falls is the vibration of the upper portion from one side to the other, under the varying pressure of the wind, which acts with immense force on so long a column. The descending mass of water is too great to allow of its being entirely broken up into spray; but it widens out very much towards the bottom—probably as much as 300 feet at high water, the space through which it moves being fully three times as wide. This vibratory motion of the Yosemite and Bridal Vail Falls is something peculiar, and not observed in any others, so far as we know; the effect of it is indescribably grand, especially under the magical illumination of the full moon.' " The whole of this region is indeed replete with interest to the traveller and naturalist, and the number of tourists who have visited it have increased from about twenty adventurers in 1855 to over 13,000 in 1882.

ENDIVE, IMPROVED ROUND-LEAVED BATAVIAN.

THIS is the best Endive grown. For years we cultivated many sorts, and in the course of time they were reduced to two, the above and the Moss Curled, but now this is given up, and we never had a greater supply or better Endive than from the one first named. Many amateurs, and single-handed men too, who have come to us to assist them in their seed lists, have been equally pleased with the result of being confined to this Endive. It is a hardy robust grower; other varieties being eaten by the snails when this is passed by. Especially is this the case when the plants are small and before they are blanched, but after that they are as tender as newly grown Chicory and as delicate as the most delicious spring Lettuce. Our first plants were ready in October, and now we have many perfectly sound which would remain good until Easter. In the early part of the autumn we tied them up to blanch, but of late the large heads have become so white in the centre that this attention has been dispensed with. Rain does them no harm, and they are less liable to be injured by frost than any variety I know. Two ordinary plants of this variety will make as much salad as six or eight of the curly kinds, and with plenty of the Batavian and Mustard and Cress no one need care much whether they have Lettuce or not for their winter salads. It is not the most seasonable time to speak of cultivating such plants, but it may serve as a hint for those now ordering their seeds.—J. M.

CULTURE OF SIBTHORPIA EUROPÆA VARIEGATA.

THE variegated form of *Sibthorpia* when used effectively in the decoration of hanging baskets or as a wall-creeper in a greenhouse is not easily to be forgotten, and one which invariably inspires those who see it with a determination to imitate, and if possible succeed in producing a similar result. Well-grown plants are, however, rare, and although the value of the plant for this work is both well known and appreciated, failure has hitherto attended many attempts to establish it in private gardens. With me this plant has been most satisfactory, and that in the vicinity of London, too, where its successful cultivation has long, I believe, been considered impossible owing to the heavy fogs and generally smoky condition of the atmosphere. Two of the most obvious if not the only

Fig. 19.—SENTINEL ROCK, YOSEMITE VALLEY.

has received a large share of attention, with the most gratifying results. The culture of cereals also forms one of the chief employments, Wheat attaining great perfection in nearly all districts. Not only can all the ordinary European products be obtained in perfection, but many sub-tropical fruits can be grown successfully, a wide range of plants suitable for cultivation being thus available. To exemplify this Mr. W. G. Kingsbury, the European emigration agent for California and Texas, 41, Finsbury Pavement, London, has for some time had a small museum of Cali-

real causes of failure are due in a great measure to syringing and giving the plant water over the foliage, together with growing it in a too humid and overheated atmosphere. It is true that until the plants are established they require to be kept rather close, but a handlight is quite sufficient for this purpose even in a cold frame.

It is most readily and satisfactorily propagated about the end of August or beginning of September. The cuttings, which should be taken off the points of the overhanging shoots, should be placed closely round the edge of the pots in which they are intended to be grown, plunging under a bellglass or handlight as above stated. No water will be required for the first two or three days, and then only the material in which they have been plunged will require damping. In April or May they will be ready for the house, and if arranged alternately with *Isolepis gracilis* on the front stage their gracefulness never fails to repay labour. Dipping the bottom of the pots in a tank or other vessel is the best means of supplying them with moisture. With regard to growing the plants on a wall, all that is required is the displacement of a brick near the top and introducing some soil before planting. In one season I grew a plant in a large pan measuring nearly a yard in circumference in a cool frame.—M. S.

"SINGLE-HANDED."

As will be seen by the under-mentioned letters, there is practically no hope of the recovery of the worthy man who by his able writings under the above signature has attracted so much attention, and whose exceptionally painful case has evoked so much sympathy.

His sorrowing wife expresses her "deeply grateful thanks to all who have aided, and whose kind acts and loving sympathy have cheered my husband through many an hour of loneliness and pain. He is sinking fast. We get no more than a simple 'Yes' or 'No.' We can only await the end now. He has left the world and all behind and awaits the summons calmly. He has often said he had no regret in leaving the world but that he was leaving his children unprovided for. We can only trust to the promise God has given us that He will be a Father to the fatherless, a Husband to the widow. I have clung to hope as long as there was a ray left, but one by one my props have been knocked down, and I can only cling to my Maker and weep."

The following letter has been received from the medical attendant of our afflicted friend.

"124, Western Road, Brighton.
"February 4th, 1884.

"DEAR SIR,—Your correspondent, whom I saw yesterday, is again much weaker than he was when I wrote to you a week ago; he has hardly strength enough left to speak aloud, and the end cannot be far off. He has been suffering much pain during the past week, and is certainly beyond all hope of recovery.—Yours faithfully, ALLEN DUKE."

To all who have aided in this extreme case of misfortune my earnest thanks are tendered—to the kind-hearted "Lady who Loves her Garden," who helped so well; to the noble marquis who increased his excellent gardener's gift; to head and under gardeners who have joined in this good work; to the "poor clerk" who sent half a crown—in fact, *all* are thanked for their welcome, because really needed, assistance.

My object was first to aid our friend in the hoped-for convalescence, and failing this to meet the necessarily great expenses that must be incurred, and in assisting the family back to Scotland. I have now hope of being able to effect this, to a very great extent at least, and with a few other contributions that may be kindly sent, to effect it wholly. That is my desire.

I have to add that it is the wish of our friend that all helpers who desire seed of his hardy border Alpines should have it, and a further supply will enable me to send a pinch to those who have failed to obtain a packet, and who will be good enough to enclose a stamped directed envelope for its transmission.—J. WRIGHT, 171, Fleet Street, London, E.C.

THE NOTTS HORTICULTURAL AND BOTANICAL SOCIETY.

THE second annual dinner of this healthy county gardening Society was held on Thursday the 31st January in the dining-room at The Arboretum, Nottingham. Six o'clock was the hour appointed, and on assembling together the very first thing that struck the observer on entering the room was the, so to speak, characteristic—the professional individuality of the whole appearance of the place, and the decorations of the tables. The floral arrangements were most artistic, the centre-piece in front of the Chairman being a masterpiece of excellent taste in the disposition of flowers (which were of the rarest and choicest) and foliage with which it was set up; and the plants, chiefly *Aralias*, *Crotons*, *Dracenas*, and *Ferns*, were of that exact size and so proportionally put about the tables as showed that the gardener decorators who had arranged them were no novices in the art of dining-room adornment. There was a brightness of beauty that had an imposing effect on everyone who entered the room. The dinner need not be described, except that it was what might be expected from so experienced a caterer as Mr. Rodgers of The Arboretum Refreshment Rooms, and the Society for whom he had prepared it.

The Chairman of the evening was the President of the Society for the year 1884, Mr. Alderman Manning, the Mayor of Nottingham; and surely no better, no more genial, no more garden-loving, no more

happiness-diffusing a Chairman could have been found. It was only needful to look on his cheering countenance to see that if "he was no gardener," as he humorously lamented later in the evening, yet that the spirit of gardening was in him, and that he loved gardeners and all their works, and was for the time being glad to be in their company. His speeches overflowed with happy good humour, with kindly wit,

Fig. 20.—YOSEMITE FALLS.

and with words of golden wisdom, and (it is not saying a word too much) the success of the dinner was largely due to the admirable manner in which the Mayor of Nottingham presided.

His supporters were men of the right stamp—true gardeners or garden lovers, such as Mr. Councillor Baines, Mr. Booth of the Nottingham School Board, Mr. Thacker (the first Chairman of the Society), the Messrs. Pearson (Alfred and Charles) of Chilwell, Gadd of Wollaton, Belliss of Newstead, Anderson of Clifton, Edington of Woodthorpe, and many others—gardeners of every degree, from the highest in gardening position in the county down to the humblest under gardener, with market gardeners and allotment gardeners, tenants of the Nottingham

Corporation scattered amongst the lot. It was a goodly and a representative company of the gardeners of Nottinghamshire.

The toast list was well drawn up, giving opportunity for the saying of good things; for loyal sayings, in "the Queen and the Royal Family," with the singing right lustily from warm hearts of "God Save the Queen" and "God Bless the Prince of Wales;" in appreciative sayings, as "the Army, Navy, and Reserve Forces," and "the Houses of Parliament;" in professional sayings, as in "the Nottinghamshire Horticultural and Botanical Society;" in congratulatory and complimentary sayings, as "the President of the Society;" in municipal sayings, as "the Town and Trade of Nottingham;" in dutiful sayings, as "the Ladies;" and in rightful sayings, as "the Press;" besides many others which suggested themselves as the evening advanced.

These toasts were all proposed and responded to with much heartiness, and with a freedom of thought and language which speaks well for the debating powers of the members of Notts Horticultural and Botanical Society—a fact that was borne witness to by the proposer of the toast of the evening, "the Society," when he said that "he had attended a few of the monthly meetings of the Society, and was much struck by the intelligent way that the members expressed themselves in the discussions, the admirable way the debates were carried on, and the depth of reading and breadth of observation which enabled the speakers to take their part in the business of those monthly meetings, which were to him so highly creditable and interesting."

The speeches were interspersed with songs, many of them from gardener singers, and all showing good taste in the selection of the song and the rendering of it, and much study and practice in the cultivation of the voice. The whole evening was a very happy one, and everyone, from the Chairman down to the humblest gardener present, appeared to catch up the spirit of the meeting and cultivate it. Though the weather outside was wet and damp, having interfered with many being present, and giving prospect of a miserable walk or ride home, these disagreeables did not mar the harmony of the evening.

The menu and toast list had been specially designed and printed for the Society, and were most appropriate, suggestive, and excellent.—N. H. POWNALL.

PRIZES FOR EARLY-FLOWERING CHRYSANTHEMUMS.

I HAVE just received from the Crystal Palace a schedule of prizes, and among those for the Show of September 5th and 6th, 1884, at p. 12, No. 7, are the prizes as follows:—For collections of early-flowering Chrysanthemum indicum (to be sufficiently in flower for decorative purposes), not less than six varieties, three plants each, and grown in 8-inch pots. First prize, £4; second prize, £3; third prize, £2. Now, as far as I know, these are the first prizes ever offered in this country for early-flowering Chrysanthemums, I think this should be more widely known than it can be through that schedule alone. Any person who may wish for more particulars should apply to Mr. W. G. Head, Garden Superintendent, Crystal Palace, Sydenham.—W. PIERCY, 89, West Road, Forest Hill, London, S.E.

CHOU DE BURGHELEY.

LIKE all new introductions this has been favoured with much attention of late; some asserting it to be inferior to the most ordinary Cabbage, while others have extolled its qualities to the utmost. I do not say that those who have written against it had no cause to do so, as by some means or other their produce may have turned out entirely different from what was expected. I am certain this is no fault of the vegetable, and the same difference occurs in many vegetables besides Cabbage Broccoli. Take Celery for instance. May not the very best variety ever introduced often be found soft and pithy with one cultivator, while with another the same variety is hard, crisp, and delicious? In this way I am inclined to account for the variation in the quality of the Chou de Burghley. It has been cultivated in our garden since some time previous to the award of the certificate until now, and from first to last it has shown a distinct, true, and superior character. In fact it has at all times corresponded with the description of the raiser, and I do not think any more than this can be expected from it. I would briefly recommend it as being superior to any Cabbage, a good substitute for Broccoli in winter, and a vegetable which merits cultivation in every garden.—A KITCHEN GARDENER.

FLOWER SHOW SCHEDULES.

THE managers of flower shows will now be thinking of revising and issuing their prize lists for the season. It is a very difficult matter for a committee, no matter how careful they are, to issue a schedule faultless in the eyes of all parties. Some public discussion on such matters may lead to good results, as it has done in the past, for of my limited experience I could point to reformations being effected with great advantage from their being brought to notice in your pages. I venture to make a few remarks on the schedule of the Brighton and Sussex Horticultural Society in hopes that they may prove of some general interest to others who may have to be subjected to similar rules and circumstances; and if exhibitors would express their opinions freely and fairly committee-men are not so blind to their own interest as to turn a deaf ear to their complaints.

In your report of this Society's September Show you made reference to the falling-off in the number of entries. I think I can point to one

reason for this falling-off. To those who "go in" for exhibiting a two-days show is thought nothing of; but to the great majority of those who come together to make up such local displays as that at Brighton a two-days show is rather a disadvantage. Until last year I think Brighton was simply a two-days show, but now it is virtually a three-days show to the exhibitor. Instead of closing the show at an early hour in the evening of the second day, it is now stated that "all exhibits must remain untouched until the morning of the third day, in consequence of keeping the show open until 11 P.M. on the second day." And they are not content with this, but they must needs pay the prize money on the second day to make sure of having exhibitors present all three days. Now three journeys, if only a short distance, and three broken days, will not pay the small exhibitor who simply wants an outing, and takes a few exhibits to try to get his expenses out of them. It would pay him better to simply pay a shilling the second day to see the show, and meet friends he has been accustomed to greet on such occasions, and be content to drop out of the list. Few would object to the two days, because a gardener may take a few dishes of fruit or boxes of cut flowers, see the show, meet his friends, and otherwise enjoy a holiday, and on the second day give his young man or men a similar outing, and let them bring home the exhibits. I think the Committee should carefully consider what money was taken at the doors after 8 P.M., and see if it would not be advisable to close the Show at that hour, as even then a great number of exhibitors of small things could reach home by late trains.

When I saw the excellent display of Grapes staged at Brighton last September I thought it was a great pity that the wording of the schedule prevented any other than Black Hamburgs and White Muscats from entering into the competition. It is no doubt more satisfactory to judges and competitors when only bunches of the same Grape are staged in the same class, and this should be followed as far as possible; but I think it is a mistake to exclude all other sorts at a September show. I think it would give a much more interesting show of Grapes to reduce the number of bunches of Black Hamburg Grapes and Muscats, and offer prizes for a few other popular sorts, while two bunches well shown show the quality of the fruit as well as six bunches.

The question of entrance fees might also be reconsidered with advantage. When we consider that the promoters of great shows are reducing, and many doing away with entrance fees altogether, I think the Brighton tax on exhibiting is rather heavy. In the "All-England" division there are ten classes taxed at 2s. 6d. each, while all the others, forty in number, are 1s. each, and similar amounts have to be paid in the "County" division for smaller prizes. I am not an advocate for the no-entrance-fee system. I think exhibitors entering into competition with some prospects of gain should cheerfully subscribe to the funds of the Society, but I think it should be in the form of an annual subscription, constituting membership.

While writing on this subject it has occurred to me to mention a rather curious mistake that was made in the schedule of the Brighton Hove and South of England Chrysanthemum Society. In Rule 1 it is stated that the entrance fee will be "2s. 6d. for the first entry, 1s. 6d. for each subsequent entry (members free)." On seeing this it was natural to inquire what constituted membership, but, strange to say, there is not a word in the schedule conveying this information. I have since the Show been informed by a friend that by subscribing 5s. you become a member. If this be so, all exhibitors will become members, and many who do not intend exhibiting should also do so, for I find by the schedule that members get a free pass and one ticket for his 5s. For this sum he will not only have the pleasure of examining the exhibits, but will also have the pleasure of listening to some excellent music—in fact, he has four miscellaneous concerts.

I was very much pleased with this fresh effort to popularise the Chrysanthemum at Brighton. I understand that it has been chiefly promoted by the younger members of the Brighton gardeners, and it must be admitted that their first show was a good one, and that they showed considerable ability in conducting it and in providing acceptable amusements, so necessary to the success of such gatherings. I hope to see such another show next autumn. I also hope that these shows will be financial successes, and that the Dome and the use of the organ will be granted on as easy terms as possible for so useful a purpose.—A MID-SUSSEX GARDENER.

FLORISTS' FLOWERS.

As time rolls on it brings with it many changes, and I think that amongst those changes in which horticulture is concerned is the light in which even a veteran regards exhibiting. Exhibitions may please, and do please, for the love of flowers does not wane as years increase; but the desire to engage in the contests of the exhibition table, as far as my own personal observation goes, does certainly diminish. The trouble and worry that sat lightly upon us in our earlier days are become invariably a burden now, and as we think of what it involves we come to the conclusion that the game is not worth the candle. The small ambitions of former days no longer kindle a flame within, and we are contented to be snuffed out by younger and abler hands. I have never been much of an exhibitor, and I must honestly confess never a very successful one—indeed, there are but two flowers in which I have ventured upon it, the Auricula and the Gladiolus. The latter has simply disappeared from the schedules of our metropolitan societies, because of

late years there has been no competition, so that even the Crystal Palace Company did not include it in their autumn show last year; and yet it was there that the best exhibitions of the flower have been held. As to the Auricula, it has never, perhaps, in its history been so largely exhibited as within the last few years; but I have come to the conclusion that a small grower like myself has not the ghost of a chance now-a-days. I cannot afford to grow the large battalions which so many possess; and although by a fluke one may take a prize, yet I hold that in the long run the chance of the small grower must be a small one. "But why not grow a large collection?" it may be said. "It is your own fault you don't know how to propagate them, and hence when you complain of large growers it is simply a proof of your own incompetency." It may be so; but when we grow a number of plants, as I do, where space is limited and money still more so, a couple of frames full are about all that we can attempt; and with this, although classes were expressly made for small growers, we find exhibitors who grow their thousand plants entering into competition with one who counts them by dozens only. But I hasten back to my former statement, and say that when one gets half way through the seventh decade a fair excuse may be put in for not undergoing the fatigue and worry of exhibiting; in fact, I know but few exhibitors (amateurs) who do so continue.

My reason for prefacing my remarks on work amongst florists' flowers at this season with this statement is, that in anything I may say as what is to be done at any particular season, I shall have only the growing and not the exhibition of the flower in my mind. It need not be said that there is much difference in the two methods. If we "go in" for exhibiting, let us say, Auriculas when the collection is small, regard must be had to the state of the plants as to their time of flowering—the plants must be retarded or pushed forward, according to the circumstances of the season; while he who grows only for the love of the flower itself is perfectly indifferent as to when they bloom. He can see without dismay the plant of George Lightbody, which was the *spes gregis*, day by day losing its freshness, while the day of exhibition is still a week distant; or his "Lancashire," which, had he that on exhibition, he would have hoped to be in, still remains with its pips unopened. When a grower has his twenty or thirty of each of these varieties he may be indifferent about it. Not so the small grower who has to depend on two or three; moreover, he may be more anxious about the size of his blooms—a fair-sized truss and pip will please him just as well as one of the orthodox size. I do not in the least write against exhibiting. I am persuaded that there is nothing which tends more to the popularity of a flower than its being brought forward as an exhibition flower; indeed, I daresay some will say that I am like the fox who lost his tail, and that on failing excuses for my own want of the caudal appendage, I am only looking out for reasons why it is so very desirable to be without one. Be it so; I must bear the reproach. The active season for florists' flowers is now at hand, and foremost amongst those demanding our attention is the

AURICULA.—The season for top-dressing has now arrived, and in both large and small collections this indispensable operation has to be gone through. In former days I have known the compost used to be very rich; but the older florists recognised, what I believe is the true state of things, that it is better to use a compost containing a little more loam than in that used for potting. Ever since the advent of that troublesome pest the woolly aphid I have at the time of repotting turned the plant out, and when I found any of them on the roots have rubbed them off, and have been very particular about clearing them away from the collar of the plants. The surface should be removed to the depth of an inch or more, but the roots should not be injured—indeed, disturbed as little as possible. Care must be taken that the soil in the pots is not too dry before the top-dressing is put on, and then the top-dressing applied to be gently pressed down and a watering with a fine rose given, so as to settle the soil; taking care, however, to wet the foliage as little as possible. Of course, all withered leaves will have been previously removed. The pots may then be replaced in their frames facing the south; but care must be taken, notwithstanding the extraordinary weather that we are now experiencing, that the frames are covered up at night, for although frost does not injure the plant it is very injurious to the evenness of the blooms, making them rough and crimply. Where there is the convenience for so doing, their removal into a pit where the grower can walk in and see his plants, no matter what may be the state of the weather, is very desirable; besides, they show better in such a position, and the pit can be afterwards utilised, as I have done mine for growing Tomatoes very successfully.

CARNATIONS AND PICOTEEES.—The same reasons (saving of trouble and expense) have determined me in future to grow these in beds instead of pots. It was the way in which I recollect in my boyish days that one of the finest collections I remember seeing in those days was grown, and in the north it is a very common practice. It has, of course, some disadvantages, notably in layering, as the person who performs that operation has to sit or kneel on the ground when doing it. Nor is there the same safety from wireworm that there is when grown in pots, for then the compost can be carefully hand-picked; but this is not very easy when grown in beds. Happily, my own garden is not much infested by them, but it is a safe plan to put pieces of Potato or Carrot in different places in the beds just under the surface to trap them. My own plants are now in their winter quarters, and I do not ever remember seeing them more healthy, with less decaying foliage, and quite free from spot. I shall not plant them out until the beginning of March, and then place hoops and a calico covering over them for a short time. Care must now be taken that they are not allowed to get dry, and also that aphides are not allowed to increase. The frame should either be fumigated or the insects brushed off with a camel's-hair pencil.

PANSIES.—The change which has taken place in the taste for these is very remarkable, the Fancy Pansy having to a large extent superseded the old white and yellow ground Show varieties, and one can hardly wonder at it. They are hardier, more striking in colour, larger, and have been now so improved in form as to present that circular outline so dear to the florist. My own small collection is divided into two parts; one is in a bed, the other in pots. These latter I have recently transferred to their largest pots—that is, into 32's, in a compost of two-thirds loam, one old hotbed manure, and a little sharp sand. They are now making vigorous growth in a frame facing the east, where they can be exposed to the morning sun but can be closed in at night. Where this operation has not been completed it should be seen to at once. Sticks should be placed to the longer shoots, or else these should be pegged down, as long shoots straggling about are very untidy.—D., Deal.

ELECTION OF CARNATIONS AND PICOTEEES.

THE ELECTORS' RETURNS.

[The names of the raisers of the varieties in the following lists have been given in the preceding election returns.]

From Mr. W. M. HEWITT, Chesterfield.

CARNATIONS.

Scarlet Bizarres.

Admiral Curzon

THE INSECT ENEMIES OF OUR GARDEN CROPS.

THE ASPARAGUS AND THE CELERY.

It is somewhat amusing to notice how surprised many persons are who have but a small knowledge of either botany or gardening when the Asparagus in its summer growth is pointed out to them, and they are told this is the plant of which they have eaten the heads during the spring. Their looks probably convey the impression that they had fancied Asparagus grew in Mushroom fashion, throwing up the tops which are cut for the table, but dying off soon or directly after these are cut. The plant when in its full foliage is certainly a pretty sight, and to a lover of Nature perhaps its beauty is rather increased by the numerous beetles that may be seen enjoying themselves, seemingly, amongst its feathery tufts; but these little objects noticeable upon the plants in July, August, or later, do not convey pleasure to the gardener's mind. They tell

of past mischief done to the Asparagus, and foretell further damage should they be left unmolested. The presence of the beetles, however, would not necessarily imply neglect, for they will occasionally travel from garden to garden, also it might happen that the grubs which lurk insidiously upon the shoots have escaped notice owing to the positions they have occupied whilst feeding: and the species appears to be more common some years than others, much depending upon the weather in the early part of the season, I suspect, for should the spring brood be checked the later broods will be few in number.

The Asparagus beetle, *Crioceris Asparagi*, has a resemblance to the familiar "ladybirds." The head is black, the thorax reddish-brown dotted with black, and similar colours appear on the wing-cases, which, in addition to spots, have two black bars crossing each other, hence some have called the insect the "cross-

Fig. 21.

bearer" (fig. 21). It feeds a little upon the leaves, but the principal mischief is caused by the grub or larva. To remove and destroy the beetles is therefore important, as checking the deposition of eggs. These may be now and then seen in rows upon the shoots, though very small, or on the flower-buds. They fall readily from the plants, so they can be shaken off into cloths or trays below. Some advise strewing lime freely over the plants after rain, as this will kill them.

But the grub is not easy to be dislodged, for it holds firmly to the shoots by its short legs and curved tail. This is of a greyish brown colour, the head being black; if alarmed it discharges a liquid from the mouth. We seldom detect it upon Asparagus till June, but the larval life is short, about two or three weeks, and when full-fed it descends to the earth, making a cocoon just upon the surface. The June brood of grubs is followed by at least one or two more. If these are not killed off, the application of soot mixed with a little salt to the ground when they have gone down will prevent their emergence as beetles, or the grubs may be dealt with on Miss Ormerod's plan, soot being laid down to receive them, and the Asparagus plants syringed with water warm enough to loosen the insects from the shoots. These may also be gently tapped. Syringing with a solution of paraffin has been successful, and in very bad cases it may be necessary to dust the plants once or twice with powdered white hellebore. Of course neither of these applications could be used during the cutting season.

The eaters of Celery, as well as its cultivators, are well aware of the fact that it has an insect enemy which devours the stems, or at least makes tracks and passages through these, the surfaces bitten by the maggot turning to an unpleasant red colour. It also mines in the leafstalks, being very noticeable upon the Celery from the end of autumn until spring. If we pull up a plant that we suspect is infested, there are usually signs that the maggots have commenced operations below and worked upwards. On examining a maggot it is seen to be legless and of a yellowish colour, with a horny head that can be withdrawn into the body at times. It is full-grown in spring, and the fly appears during May. This has a black head and body. Upon the latter are fine golden hairs, the wings colourless, excepting the veins. In size it nearly resembles the Celery leaf-miner next to be mentioned, being about half an inch across the wings when these are expanded. No means have proved very efficacious in warding off attacks from this fly. The prompt removal and destruction of all infected stems seems the only plan to diminish their numbers.

The fly of the Celery leaf-miner, *Tephritis onopordinis* (fig. 22), has also transparent wings, but with tiny brown patches upon them. The head and body in this species are brownish, eyes dark green. May appears to be the month when it is particularly abundant, though there is a later brood, or possibly two; the maggots growing rapidly when the summer is of average warmth. Towards the autumn a few linger on in the leaves, but most of them descend to the earth before the cold nights of autumn, remaining there as pupæ through the winter months. This maggot or larva, which is legless, whitish green, blunt at the tail, with sharp retractile head, shows itself by producing blisters upon the Celery leaves. These patches, first white and afterwards brown, are sufficiently visible for children to be employed in pinching the leaves infected, and hundreds or thousands may be thus killed. If the operation, however, is performed carelessly or hastily, the plants are likely to be as much injured almost as if the maggots had been left untouched. In some cases the plants are positively killed by this pest, especially

where water has been scant and manuring not well attended to, because the new growth does not then replace the leaves that have perished.

One of the correspondents of this Journal states that he has found brewers' hops a good preventive. When the Celery seedlings are pricked out he sprinkles some hops amongst them, and at the time the plants are removed to the trenches he puts more between the rows. This seems to keep the flies from approaching to deposit eggs. Also the leaves may be dusted with soot, lime, or other substances which are likely to keep them from settling upon the young plants. The winter is an important season for operations, since many pupæ are lying then in the earth just below the Celery, hence the advantage of scraping off the surface and of rough digging, which buries some too deep for the flies to emerge, and brings others within reach of birds. Or gaslime may be used to give the soil a dressing; this will kill most of the pupæ. The Celery fly has a parasite which reduces the number of the pupæ that produce the mature insect. It appears to attack the larvæ, placing one egg in each; they turn to pupæ, but the enemy within ends their life in this stage. This useful species is called *Phagonia smaragdina*; it is a beautiful object under a magnifier, of a golden green, having the antennæ and legs bright orange. Some years the blisters of this leaf-miner are not uncommon upon the Parsnip also, a plant which does not seem to have any foes peculiar to itself, but which is sometimes infested by the "rust" of the Carrot (*Psila rosæ*), and the two species of *Depressaria* which visit the flower heads

Fig. 12.

and seed of the Carrot occur upon the Parsnip as well. That very general feeder on roots and stems, the wireworm, larvæ of one or other of the click beetles or *Elaters*, occasionally touches Celery, but much prefers Carrots or Turnips when they are handy. I have not found the Celery attacked by the subterranean caterpillars of those common garden moths, the Turnip moth (*Agrotis segetum*), and the Dart (*A. nigricans*) though it would be no wonder if such were the case. — ENTOMOLOGIST.

PEACH TREES CASTING THEIR BUDS.

IN reply to "Alpha," I may state that for more than a dozen years I used nothing but spring water for watering the indoor borders of Peach houses, and it was never warmed or brought to the same temperature as that of the house in which the trees were growing, but it was distributed by a hose pipe just as it came from the cistern into which the spring delivered, and as the cisterns were underground the temperature of the water was rarely more than 50°. This may seem strange as applied to Peach trees forced to ripen their fruit in May or early June, and still stranger to syringe the trees twice a day with the same water at the same temperature. It may be considered contrary to sound practice, and yet I never noticed any sensible difference in the results when the trees were watered and syringed at the same temperature as that of the house or when they were supplied with the cold water. Did the buds fall? Yes, some of them two years in the fourteen, yet it did not occur to me that it was due to the spring water; in fact it was not, as the buds were cast in one of the years when tepid water was applied—viz., in the fourth year from planting, and in the eighth when they were supplied with the cold water. The buds were cast just as badly with the warm soft water as with the cold spring water. This may appear remarkable, yet it is not in the least perplexing, as the trees had attained in the third year to such a degree of luxuriance that the wood did not ripen, and some of it was fully 6 feet in length, and nearly as thick as the thumb. The buds were cast for the most part from the weaker wood, double and even triple fruit buds coming off in a shower. The buds on the strong wood, though they remained, expanded into deformed flowers deficient in the organs of fructification, some with two and even three pistils, and the anthers defective in pollen. Although fertilised with pollen from other trees, the set was very indifferent, and fully nine-tenths of the fruits fell during the stoning process. The growths were magnificent, leaves 9 inches long and 3 inches across at the widest part. They were well fed and well watered. It was

clear what was wrong. The borders were too rich, too wide, and too deep. It is a common error, and more disasters are attributable to this cause than any other, as when the roots are in wide deep borders they make more wood than is needed for the due extension of the trees or for insuring a supply for future bearing. The roots go down deeply, and no mulching in that case will attract them upwards. The drainage was all that could be desired, and the border also as regards materials, only there was too much of it, and if it had a fault at all the compost was too rich.

I did not see my way to alter the border, therefore set to work to alter the trees. Consequently as soon as the wood had become a little firm a trench was taken out a yard from the stem all around down to the drainage and every root cut off. The trench remained open about a fortnight, care being taken that the circle did not lack moisture during that time. This put a stop to all further growth, and the need to stop laterals ended. The surface soil before filling in the trenches was removed down to the roots and some of them brought nearer the surface, but not many. The trenches were then filled up, a good watering given, and the buds swelled plumply. No buds were cast, not even of *Noblesse*, *Grosse Mignonne*, *Bellegarde*, and *Barrington*, the former being one of the worst bud-casters known. The set was good, and the stoning most satisfactory.

In the eighth year the buds began to fall again, the roots were too strong, and the wood was corresponding. Lifting was resorted to, and so severe were the checks that despite keeping close, syringing, and shading, some of the wood shrivelled slightly, but it was only temporary, for when the roots were in action again it plumped up and the buds also. No buds fell, and the set and stoning were all that could be wished. No more buds were cast, for the simple reason that when the trees showed any tendency to over-luxuriance they were lifted as soon as the wood became firm, and then the wood ripened and the buds formed perfectly. This is one side of the question; there is another which I shall presently allude to, but before doing so would like to point out that when a Peach tree makes strong wood (and there is nothing like it for obtaining fine fruit), the trees being on the extension system there must be more space allowed between the shoots, so that the foliage may have full exposure to light and air, for when the growths are crowded the wood, for want of those elements, is not solidified, and never has a chance of becoming ripened. This is a very prevalent error, and cannot be too often pointed out with a view to its avoidance.

Then Peach trees cast their buds most frequently, it must be allowed for lack of nutrition, especially of the great solvent—water. This is by far the chief cause of Peach trees casting their buds. We very often see water given plentifully when the buds are swelling, and not infrequently it serves no purpose, except to cause them to fall. They have been dry at the roots all the winter, the house has been kept dry, the wood has been losing moisture all the time, and the buds have been literally starved to death—dried up. When the watering is given the sap is drawn or impelled upwards, and it serves no purpose but to push off the buds, simply because they have no channels to receive the nutriment which in their case comes too late. The roots of Peach trees are always more or less active, and to keep them dry when the trees are at rest is to jeopardise the buds.

There is another aspect of the question—viz., Peach trees casting their buds from imperfect development in embryo. It is a mistake to keep the borders well supplied with water up to the fruit ripening, and then begin to diminish the supply or allow, as is sometimes done, the border to become dry with a view to ripen the wood. Until the fruit is ripe, or nearly so, very little is done by the trees towards bud-development, but as soon as this is effected the vital force seems concentrated on the fruit buds, which swell with amazing rapidity. This is the time when the roots need moisture, and if the trees have carried a heavy crop give them liquid manure, also removing all wood not required for the next year. This serves the twofold purpose of concentrating the strength on the buds for future bearing, and by admitting more air ripens the wood perfectly. We conclude, therefore, that the soil in which Peach trees are growing should never be allowed to become dry; more particularly is this the case when the buds are being plumped than during the earlier stages of their formation.

Lastly, Peach trees cast their buds through the foliage being allowed to become a prey to red spider; the leaves in that case are not able to perform their functions, and they collapse ere the buds are perfectly formed.—G. ABBEY.

RELATIVE to Peach trees losing their buds, may I inform "Alpha" that I have been troubled in the same way with trees in pots? Consequently last season I resolved to give them a natural winter's rest out of doors, and I am sure there cannot be better-looking buds anywhere. I would advise your correspondent to give his trees more water, which would help them but not save the buds this season. Next autumn and winter he should keep the border moist so that the roots can keep the tree and buds well charged with moisture, as a tree naturally is outdoors, as if the roots are dry then the buds will fall in the spring.—J. H.

HAVING read in the Journal several complaints under the above heading, I am sorry to report that similar cases have recently come under my notice with trees grown under glass, but the trees on the walls outside do not appear to be affected in the same way. I believe that deficiency of water at the roots at some period of their growth is the cause of the disaster, that too little attention is generally paid to the condition of inside borders after the crop is gathered, and that as a rule they are kept too dry when the trees are at rest. I should be glad to hear if your

correspondent's trees, both inside and out, are affected in the same way.—L. T.

HARDY PLANTS IN FLOWER.

CHRISTMAS ROSES.—The numerous species and varieties of *Helleborus* to which these belong are a most interesting and useful class of plants, especially *H. niger* and its varieties, which are so valuable on account of their white flowers coming in when everything is dull and cheerless outside. There are many other varieties of *Helleborus* which are much less generally known than *H. niger*, which, nevertheless, are very desirable for the hardy flower garden, withstanding wind and weather, and you stand and wonder how they managed to select such a dreary time in which to unfold their flowers.

Helleborus niger.—This protean species is to my mind indispensable in the flower border, and the variety *altifolius* is perhaps as distinct as any, with mottled stems and large flowers tinged with pink outside. Very much is written to little purpose as to the varieties, for after all we have not been clearly informed which is the typical form, and great efforts have been made to establish varieties, until we are left to wonder which are in the greatest confusion, the writers or the *Hellebores*. In the case of *H. niger* there are so many variations that, in my opinion, it is impossible to propose with certainty any characteristics for a particular variety which cannot be found in varying degree in other plants. Very recently I was looking over a large flat of some thousands of plants which were all imported at a low rate as *H. niger*; well, in that batch there is an astonishing amount of variation in leaf, form, size, colour, and spotting; indeed, I have no doubt in a few years when the plants are established all the varieties about which there has been so much writing recently might be selected from them. It is ridiculous to assume, after examining a limited number of cultivated specimens, that such and such a characteristic mark particular varieties; but when a large batch is investigated under natural conditions, such seemingly good points of difference are prejudiced by a numerous intermediate series, which makes us inclined to give up making many names and get as much variety as we can. Quibbling about varieties is unnecessary. Let us grow all we can of these most useful winter-flowering plants; and I will now add a few notes on a few other varieties of *Helleborus* which now give me great pleasure, and I think all growers of hardy flowers should have at least a clump of each of these varieties, and some enthusiasts would say a great many others.

H. atrorubens produces stems about a foot high, with from one to four flowers on a stem, each about 2 inches across, of a deep purple-red colour, slightly drooping. Very free-flowering and vigorous.

H. olympicus rubra has stems 12 to 18 inches high, freely branched with numerous flowers fully 2 inches or more across, tinged with reddish-pink outside; three of the sepals are white tinged with pink, the other two greenish white.

H. orientalis multiflorus is very free-flowering, about a foot high, the flowers from 2 to 3 inches across, reddish-purple at the back; three of the sepals are heavily shaded reddish-purple with the middle sea-green; the other two more or less of the same green, slightly shaded.

H. o. purpureus-punctatus is very free, with flowers about 2 inches across; three of the sepals purple-shaded and the middle portion thickly dotted with magenta spots. Some other varieties are out, but they are not so showy, and several others will open shortly.

CROCUSES.—The winter-flowering forms of this genus are extremely charming. Very bright are they in a dreary climate, peeping up often through a snowy covering. Several are out in flower.

C. Imperatorius grows about 3 inches high; the outer perianth divisions are pale buff, longitudinally striped with purple; the inner ones pale violet-purple throughout, contrasting prettily with the outer ones. This is most easily managed either in pots or planted out. I have now a charming pot of it. It varies a good deal; sometimes the inner divisions are very pale.

C. chrysantha is a little gem; the perianth limb is about an inch long, globular in form, with a dilation just above the tube; both inner and outer divisions of a deep golden yellow colour throughout.

C. Olivieri is similar in colour to the last; but there is no swelling at the top of the tube, and the flowers are not so rounded in form, the divisions being much narrower.

C. striatus is also another very fine yellow-flowered species of a deep ground colour, with a few paler longitudinal marks on the outer divisions. The flowers of this are large and very conspicuous.

C. minimus produces very small flowers about an inch long

or less, of a pale buff outside striped with purple. A little gem, just going over.

C. reticulatus is about 2 inches high, with long perianth limbs; the outer divisions deep orange-yellow striped with broad bands of chocolate-brown, making a very striking contrast, while the inner ones are all deep yellow. This is also a charming little species in clumps.

C. Sieberi is a variable species; but the form usually met with, as far as I know, grows about 3 or 4 inches high, the perianth limb being from 1½ to 2 inches long; both the outer and inner divisions of a clear purple-violet colour; the inner ones much broader, but rather shorter than the outer ones. It is a very showy species; sometimes the flowers are variously marked with yellow, when they are particularly striking.

MERENDERA SOBOLIFERA.—A curious and pretty little plant, with slender underground stolons, narrow oblong leaves and white flowers; the perianth divisions are very long and slender, the limb being about an inch long, oblong, upon long slender foot-stalks, which constitute the tube—a clear instance of the common origin of ordinary and floral leaves. This species may not be showy enough to please everybody, but it is one of those strange little plants which gratifies the enthusiast.

HEPATICAS.—These are charming old-fashioned favourites, enjoying peace and quietness as much as any plant, for it is only after remaining a few years undisturbed that good specimens can be obtained. In old-fashioned gardens they are frequently found in grand state, large clumps crowded with flowers. They are now, and will be for some time, flowering freely; the double red, single red, white and blue, as well as *H. angulosa* quite aglow with colour, but the double blue seems to be rather later, at least with me such is the case, as not a single flower is yet expanded. *H. angulosa* is a very fine species, with large sky-blue flowers, much finer than any of the *H. triloba* section, and it is very floriferous. The one known as *H. americana* is a very poor thing, the flowers being small and a wretched colour. There is a great diversity in the *triloba* section, some with red and white stamens, and with many shades of colour. One variety I grow under the name of *H. triloba Barlowi* is very fine, with a large circular flower of a pale sky-blue colour, in which it resembles *H. angulosa*, but the form of flower is very different. They are all well worth growing.—T.

HARDY FRUIT GARDEN.

Pruning.—Peaches, Nectarines, and Apricots should be pruned and trained now as soon as possible, for the buds are becoming so prominent owing to the mild weather as to render immediate attention to this matter imperative. This should bring the winter pruning to a close, excepting the Nuts and Filberts, which should remain unpruned till pollen is plentiful in the catkins and the female blossom is fertilised. It is sometimes advised to prune sooner and to leave a few catkins for pollen, but such advice is unsound from the fact that so many catkins sometimes perish from excessive wet weather that to leave only a few is to risk the loss of the crop. Wood for grafting should be inserted in moist soil to be kept plump and fresh, but do not cut back the stocks or branches that are to be grafted till the sap is in motion, then cut back and graft at once.

Old Fruit Trees.—Keep zealous improvers away from old fruit trees, and do not hastily remove old spurs or thin out branches. Many a healthy old tree is condemned as barren upon which fruit buds were plentiful enough in autumn, but when spring comes round hardly a bud has escaped the ravages of the bullfinches. Keep down such pests, see that the trees are sheltered from cold winds, replace exhausted soil about the roots with that which is fresh, sound, and fertile, and you may reasonably expect a crop of fruit in every favourable season.

Profitable Nut Culture.—We happen to have some soil so thin and poor that fruit trees barely exist in it. A trial of Nuts and Filberts in it affords a curious and important result, pointing unmistakably to handsome profits for a trifling outlay. A dozen plants of each sort were planted in it without the addition of any other soil or of manure. Red Filbert exists, but marks no appreciable progress. Cosford Nut attains a moderate degree of vigour, and bears a proportionate crop of its excellent thin-shelled nuts. Kentish Cob makes a sturdy and tolerably vigorous growth, and yields fair crops in favourable seasons. Pearson's Prolific is singularly robust and vigorous, most of the trees being fully 30 feet in circumference, and they are almost invariably laden with an abundant crop of nuts.

FRUIT-FORCING.

VINES.—*Early Houses.*—Tying, stopping, and thinning in early houses must be followed up, not allowing anything in those respects to get into

arrears, as it will tell later on in the swelling and finishing of the crop; and do not allow surplus and ill-shaped bunches to remain until the berries have swelled considerably, as that represents so much loss to those that are retained for the crop. Avoid overcropping and strive for quality in preference to quantity. Grapes vary so much in form of bunch and size of berry in different varieties that no definite rule can be laid down for thinning. Young Vines as a rule produce loose bunches, and will only need to have the small berries taken out—*i.e.*, presuming the shoulders are properly tied up; but old Vines, especially when spur-pruned, give close compact bunches, and require severe thinning to prevent binding when ripe; at the same time the thinning must not be so severe as to give a loose appearance, as it is important that the bunches preserve their form when on the dishes. Muscats and other shy-setting varieties should not be thinned sparingly until the fertilised berries are taking the lead, the unfertilised being readily detected by their small increase and slenderness of the footstalk.

Succession Houses.—Disbudding and tying in houses started in December must be attended to, being careful in bringing the shoots down not to snap them at the base. Any that are stubborn will be best brought down by degrees. Syringe freely on fine days, and if fermenting materials are not used in the house damp the floor and borders with clear liquid manure in the afternoon—*i.e.*, at closing time, as an ammonia-charged atmosphere is invigorating to the Vines and is one of the best preventives of red spider. With the Vine shoots an inch or two long, raise the night temperature to 60°, and 5° to 10° rise by day, ventilating from 70°, allowing an advance to 80°, closing at that temperature early along with a moist sweet atmosphere.

Late Houses.—In houses containing Vines of such varieties as Alicante, Lady Downe's, Gros Colman, &c., that have been brought into the way of starting early to insure to them a long season of rest, all painting, cleansing, and top-dressing must be brought to a close. If the outside borders are not considered satisfactory, lose no time in rectifying errors or defects in drainage or compost. Remove the surface soil down to the roots, and if these are deep raise them carefully and lay in fresh compost nearer the surface. Good turfy loam, with an admixture of old mortar rubbish, charred refuse, and crushed bones at the rate of about 20 per cent. formed into a border 6 to 8 feet wide and 2 feet deep, resting on a bed of drainage 12 to 15 inches deep, with a drain to carry off superfluous water, will give much better results than a wider and deeper border of indifferent cold material. The chief after-consideration is mulching with good manure from early May, and drenchings with tepid water when the Vines are in active growth.

CUCUMBERS.—Fresh soil appears to work wonders with old plants; hence any that are showing signs of exhaustion should have the old surface soil removed, picking it out from amongst the roots without disturbing them much, supplying fresh lumpy loam to which has been added a fifth of thoroughly decomposed manure, having had it in the house a few days to warm previous to placing it about the roots. Water moderately with tepid water to settle the compost about the roots. Attend to the removal of superfluous and ill-shaped fruit. Tie the young shoots to the trellis and avoid overcrowding, stopping about one joint beyond the fruit, or allow more extension if there be room. Remove bad leaves as they appear. If there be any red spider remove the worst infected leaves and coat the pipes thinly with sulphur brought to a thin cream with skim milk, but be careful not to overdo it or the fumes of the sulphur will injure the foliage. Maintain a bottom heat of 85° or 90°, give air on all favourable occasions with care and judgment, and close early, damping the floor so as to cause a moist genial condition of the atmosphere.

Planting.—Young plants raised from seed early in January will now be fit to place out. A ridge of soil about 2 feet wide at base and 1 foot at top the lengthwise of the bed will be sufficient to plant in, and should be in the house a few days to get warmed through before the plants are put out. Press the soil firmly around each plant, placing a stick to each and securing to the first wire of the trellis. The heat and moisture are the same as for old plants.

Plants in Pots.—Not having a house suitable for growing plants in beds a few good fruits may be had from an ordinary span-roofed plant house kept at a stove temperature. Pots 15 to 16 inches in diameter are most suitable. Drain well and half fill with a compost of three-parts turfy loam and a fourth of well-decayed manure, dry, or at least free from worms, and about a sixth of charcoal. Place the plants in the pots, not making a hole for the roots, but draw the soil from the sides of the pot up round them. A stick can be placed to each and tied to the wires, and when the plants reach the wires secure to them and stop the shoots when a few inches of growth has been made, training afterwards as space will allow. The buds or growths from each leaf should be rubbed off when showing up to the height of the trellis, but the leaves may remain for a few days later, removing them from the upright stem by degrees as the plants elongate and from the base upwards. When the roots appear on the surface add a couple of inches of fresh soil and so on, and when the pots are fairly filled with roots give copious supplies of weak liquid manure not lower in temperature than that of the house.

MELONS.—The plants that were placed out in hot-water pits, instead of shifting them into larger pots, as is advisable when they are intended for trellises, are making steady sturdy growth, and to keep them sturdy should have a little air in favourable weather. Plants that have been shifted into larger pots and grown on until they are a foot to 15 inches high for transferring to hillocks or ridges in the Melon house, will be ready for putting out. Press the soil firm around the roots and endeavour to obtain quick thoroughly solidified growth. A top heat of 65° to 70° at night, or 5° less on cold nights, 70° to 75° by day, with an advance of 85° or 90° from sun

heat, admitting a little air on all favourable occasions, and closing the house early with a moist genial condition of the atmosphere. Stop the plants when they have extended about two-thirds across the trellis, removing every alternate lateral on opposite sides of the principal when quite young, and all up to the trellis from the base. Sow for succession, keep a sharp eye on the lining of dung-heated frames, renewing when needed with sweetened material, of which a good stock should be kept by throwing into a heap fresh materials at intervals.

PLANT HOUSES.

Crotons.—Young plants that were rooted in late autumn will now need attention, and should be transferred into larger pots without delay. Where plants of fair size are appreciated in 7 or 8-inch pots as single specimens for room-decoration, select those for this purpose that were the leads of plants and well furnished with bold highly coloured foliage to the surface of the soil. Many of the narrow-leaved varieties are best for room decoration in 5 and 6-inch pots. When good well-developed plants are required for this purpose it is essential that the portions selected for rooting should be well developed and then rooted without losing their leaves. Many Crotons, when large plants are not required for the stove, are most desirable, and display to the best advantage their natural character when grown on without being stopped. This is not the case with smaller-foliaged varieties after the old Croton variegatus type, which should be stopped when inserted by removing the centre, and then allow three or four shoots to extend to form small bushes. However, plants well coloured with a single stem about 1 foot high are valuable for a variety of decorative purposes. If large specimen plants are required select dwarf strong healthy plants and pinch out their points as soon as the roots are advancing in the new compost, which should consist of good loam, a little soot and bone meal, with sufficient coarse sand to render the whole porous. If practicable plunge in bottom heat for a time after potting. Another batch of cuttings should be rooted, cutting down plants that are growing too tall for the decoration of the stove or for any purpose for which they are required. Use a little lighter compost for these—say one-third of peat, the soot being dispensed with; a little sand should be placed in the centre of the pot for the base of the cuttings to rest upon. Water after insertion, and plunge in bottom heat in the propagating frame, and keep close until rooted.

Dracenas.—Heads that were rooted at the same time as the Crotons may now be transferred into larger pots, the size of pots depending entirely upon the purpose for which the plants are required. Some grand plants can be grown in 6-inch pots, the size in which ours are grown for room-decoration, while that for the stove will when ready be transferred into others 2 or 3 inches larger. Small plants that were raised from stems and are now well established in 3-inch pots should be transferred into others 2 inches larger. Use for a compost two parts fibry loam, one of peat, and one of leaves and decayed manure, or better still, old mushroom-bed refuse in which leaves has formed a part; a little charcoal may be added and sand. Plunge in bottom heat until root-growth commences. Plants that have been used and have become unsightly may be cut up for stock. The root portion of the stem will form plants the quickest, and are not so liable to decay as the stem; the latter may be used if sufficient cannot be obtained from the former. Place them in sandy soil in pans, and stand in heat until they commence growing and rooting, when they can be potted singly. *D. gracilis* and *D. rutilans* are two of the best green varieties that can be grown for room-decoration. The last does well in a greenhouse temperature.

Solanums.—It will not be difficult to obtain a number of cuttings from the plants in the conservatory, the young newly made wood is the best for this purpose when quite soft. If taken and inserted in sandy soil and placed in heat in a close frame or in a bellglass they will soon become rooted and ready for potting. After the plants are rooted and potted singly, treat them liberally until they are bushy, ready for 5 and 6-inch pots, and can be placed in cold frames. Plants raised from cuttings are preferable to seedlings, as they bear more and finer berries. In order to obtain good plants in a season an early start should be made. Old plants that have been in the conservatory should be pruned close back, and when they have commenced growth reduce the balls by one-half and place them again in the same size pots. A good place to start these plants in is an earlyinery or Peach house.

Heliotrope.—Insert a batch of cuttings to be grown on for decoration in the conservatory. Standards or bushes that flowered during the autumn, and have since been resting, may be partially pruned and introduced into gentle heat, when they will soon break into growth, and in due time be useful again for the conservatory. Young plants struck in autumn and kept in small pots up to the present time may now be placed in 5-inch pots, and grown on close to the glass in a temperature of 50° to 55° at night. After the roots have commenced growing ventilate daily if the weather is favourable to maintain a dwarf sturdy growth. Loam, leaf soil, and a little decayed manure and sand will suit these plants well.

Petunias.—A batch of cuttings from old plants kept for the purpose should be inserted in sandy soil and placed in heat to succeed those struck in autumn and established in 3-inch pots. These should be bushy little specimens, and ready if properly attended to for 5-inch pots. The shoots may be pinched after the plants have started growth in the pots in which they have to flower, until they possess sufficient shoots to form bushy little specimens, when they may be allowed to come into flower. Use the same compost, and grow them under the same conditions as the Heliotropes.

Fuchsias.—Plants that have been at rest should be started. Give a little water at the roots, and place the plants in a temperature of 50° where they can be syringed two or three times a day. Place young plants

struck in autumn, and now established in 2-inch pots, into 4-inch pots, using a light compost. Supply each after potting with a small stake, and place them in the same house as the Petunias.

THE FLOWER GARDEN AND PLEASURE GROUNDS.

Bedding Plants to be Propagated.—Where the stock of such plants as Ageratums, Heliotropes, Koniga maritima (Alyssum variegatum), Iresines, and Coleuses is rather limited, in many cases it will be advisable to commence propagating them at once. Take off the soft-growing tops, trim to a joint, and dibble them in thinly either in well-drained pots or boxes filled with light sandy soil, the pots to be plunged in the propagating frames and kept close till struck, and the latter stood on a hotbed and covered with strips of glass. The cuttings should be watered in, but subsequently little water will be required, and if damping results either wipe the glass dry or uncover the cuttings for about an hour every morning. Pick off any decaying leaves and shade from bright sunshine. When the cuttings are struck gradually expose them to more light and air, and make more cuttings from the tops when these are strong enough, the plants to be placed in pots or boxes, using good soil, when they are breaking after this topping. Proceeding in this manner a few dozens of plants may be increased to thousands by the time they are wanted.

Zonal Pelargoniums.—These have damped badly this winter, and a considerable number will have to be struck this spring. Hard half-ripened tops do not strike root readily, and in order to secure the requisite number of softer cuttings, those to be increased should be introduced into a gentle heat. The shelves of a newly started vinery will suit them, and the cuttings later on will strike freely if the pots are placed on the shelves over the hot-water pipes. The golden and silver variegated sorts are the most scarce, and luckily the spring-struck plants of these are usually the most effective during the summer and autumn months. Prior to potting or boxing off the stock of Pelargoniums, and supposing there is no necessity to strike the tops, it is advisable to take out the points of the plants, and when they are breaking is the time to repot them. All ours, when planted out, are kept pegged down over the beds, and those who also follow this practice are advised not to stop the young plants, as the more spreading they are the better they fill the beds.

Sowing Seeds.—Seed of tuberous-rooted Begonias, Echeveria metallica, Pentstemons, Antirrhinums, Grevillea robusta, Cannas, Acacia lophantha, Chamæpeuce diacantha and C. Casabonæ must be sown early and the seedlings grown quickly in order to have them of serviceable size when required for planting out. The Begonia and Lobelia seeds are the most minute, and for these well-drained pans should be filled with sifted soil consisting of equal parts loam and leaf soil, with silver sand freely added, a little of the roughest soil to go over the drainage, the fine soil to be made rather firm, and the surface quite level and faced with a little sand. About an hour prior to sowing the seeds water the soil through a fine-rose pot, and when the seed has been thinly and evenly distributed over the surface lightly dust over a small quantity of sand, cover with glass, and stand the pans on a brisk hotbed. Shade heavily till the seeds have germinated, and if at any time it is necessary to moisten the soil it must be done very carefully, either by partially plunging in tepid water or through a fine rose, or the seeds will be dislodged.

The seeds of Echeverias, Pentstemons, and Antirrhinums being also rather small, should not be buried deeply; in fact they are best treated similarly to the Begonias, care being taken that they be kept uniformly moist and closely shaded till they have germinated. Remove the shading directly the seedlings are seen, and gradually expose the pans to more light.

Grevillea robusta and Chamæpeuce seeds should be lightly covered with fine soil, and the pots or pans plunged in a brisk and moist bottom heat. The seeds of Acacia and Cannas are usually very hard, and seldom germinate satisfactorily unless previously softened in rather hot water. If the evaporating troughs over the hot-water pipes are kept constantly full the seeds may be soaked in these for a few hours, or till they have swollen considerably; or if this plan is impossible or thought dangerous, place the seeds in bottles of water, and plunge these in a strong hotbed for at least twelve hours. The seeds being softened, they should be sown thinly in pots of light soil previously warmed, watered with warm water, and plunged in a hotbed, the seedlings eventually to be potted off singly into 3-inch pots, and receive a shift before they become root-bound. The roots of Cannas, after they have been started in heat, divide readily, but it is not advisable to start them yet unless the stock is too limited.

THE BEE-KEEPER.

SWARMING VERSUS NON-SWARMING SYSTEM.

INFORMATION gathered from all parts and from every class of bee-keepers on the above subject would indeed be most valuable. On page 53 a correspondent from Co. Down, after setting forth his own views and opinions on the matter asks, "What do others say?" We will endeavour to reply to his invitation by stating what deductions we have been able to draw from our experience in trying both systems.

If asked to give a verdict in a few words we should say, "Both systems must be employed together." The bee-master must act according to his own judgment, which will depend

entirely upon various contingencies caused either by locality, season, condition of stock, or even by quite unforeseen accident of the moment which may entirely change the system upon which a particular hive has up to that moment been managed. It is quite impossible to lay down any hard-and-fast rule for the government of a single hive, or of any collection of hives. Advantage must be taken of every opportunity offered by, for instance, an early warm spring, when stocks may be increased to advantage, and supers fill well afterwards; or of the extraordinary breeding powers of any particular queen, or again of the proximity of perhaps some acres of a particular crop which a farmer has placed nearer the apiary than usual; in fact, cases can be multiplied *ad lib.*, which will only be seen and seized by the bee-keeper after experience has taught him many lessons.

We kept bees for many years in a locality similar so far as the production of honey goes to that of Co. Down. There we had to depend entirely on a short season of plenty during which we expected our supers filled and the extractor to be constantly at work. This glut usually sets in about the first or second week in June, and was all over in about three weeks. In such a neighbourhood it was impossible to carry out a strictly swarming system, for the swarming mania usually set in in the midst of the honey harvest. Before newly hived swarms could have well got into supers the flow of honey would have ceased, and both stock and swarm would have been profitless for the season. Our habit was to drive out swarms from the most forward hives towards the end of May, and by stimulating these swarms and by the use of full sheets of foundation to build them up quickly so that the batches of young bees were hatching out just at, or a little in advance of, the advent of the honey glut. Our best supers were often obtained from these swarms. The stocks from which these swarms issued soon had fertilised queens, and invariably good vigorous ones. When we knew the queen to be fertilised we took another weaker stock having an older queen, and having destroyed this queen we united its bees to those of the driven stock, placing the young queen in possession. We then doubled the stock by placing the hive from which queen and bees had been taken on to the top of the swarmed hive, first placing all frames with drone comb on the top and the worker brood below. We kept all honey slung out from the lower combs, giving the young queen every scope to fill up the cells with eggs before the glut of honey set in. We used queen-excluder zinc between the hives.

When the harvest commenced abundance of room had been provided above since nearly all brood had hatched out, if we had been obliged to place some there. A powerful lot of bees was prepared to pounce on the nectar, and the slinger was busy every other morning, extracting every drop of honey from the top batch of combs. We always found early morning the best time to extract, the honey had lost much of its water by evaporation during the night, and required little ripening. In one or two instances we caged the queens of stocked wishing to swarm just before the harvest, but we did not find this plan answer. Two queens we remember finding dead in the cages, and both stocks prepared for swarming with a fresh batch of queens ready to hatch. As a means of obtaining a great weight of slung honey in a short time there is nothing like doubling, and by making sure of a young queen at the head of the doubled stock, that stock nearly always does well for the next season.

To a certain extent the non-swarming system may be carried out, but where the bees are very forward we think that more can be done by taking the first early swarms and doubling weak stocks. Our tactics, however, will be very different in our new locality. With hundreds of acres of Heather within reach of our bees we shall not be driven to such straits as formerly. Later swarms may now be taken, and if too late for the first harvest from fruit and forest trees, they may do wonderfully well with the Heather honey. But our aim will be now to get supers filled. It is not easy to extract Heather honey unless slung immediately after storing. Sections must be the order of the day now, and all our devices must be to compel our bees to so work as to give us the greatest possible quantity of honey in the comb. Whether honey be required in the comb or for the slinger, the aim of the bee-master must be to force the bees to put the honey where he requires it. If the bees have nowhere else to put it when honey is abundant they necessarily must place it where he wishes. Therefore he should use his utmost endeavours to try all sorts of schemes to get the brood nest full of brood and eggs in all stages, just allowing the bees space for a sufficient supply to provide them whereon to live, just at the time he knows the honey glut will set in, then only let him keep his supers warm and conveniently situated, and the honey must be put into them if it can be collected.

After all, our capricious climate may spoil all. Should a

period of wet cold weather set in and the harvest fail, well then the bee-master must live through another winter on hopes and not on honey, and more than that, he must be liberal in his supplies of artificial food, and feed up his carefully augmented army until they are fit to go into winter quarters. "Comber" seems to have done by accident exactly the same thing we used to practise as above explained. He found that the stock from which a swarm issued, and whose queen entered a strange hive and was killed, made a good honey harvest, through having a virgin queen at its head just before the glut set in. Where an increase of stocks is not desired the non-swarmer system may be thus carried out invariably to the bee-keeper's advantage. Plenty of honey will thus be obtained, and hives with young and vigorous queens continually kept over to the next season.

Like "Comber," we have generally found that a prime swarm returned, and the queen cells simply excised, was either still bent on swarming again after preparing a fresh batch of royal cells, or that they sulked for days after, and often in the end lost much of the precious honey season. It will be seen from our remarks that we do not believe that a strictly non-swarmer system can be carried out. In former papers we have shown how bees can be kept with a minimum of the desire for swarming, and how we induce them to take to supers, and therefore we will not go over that ground again, but only say that those who do not wish for swarms must be ever on the *qui vive* to adopt the many means which offer themselves at the right moment and in the right way. And one word more. Swarming is a natural habit with bees, and there is not a doubt that in localities favourable to honey-getting, in the end the most profitable method of keeping bees is to allow strong early hives to throw off a prime swarm, and the stock hive with its colony will produce more than any single stock managed on the non-swarmer system.—P. H. P.

TRADE CATALOGUES RECEIVED.

- J. C. Schmidt, Erfurt.—*Catalogue of Flower and Vegetable Seeds.*
 E. G. Henderson & Son, Maida Vale, London, W.—*Catalogue of Vegetable and Flower Seeds.*
 W. P. Laird & Sinclair, Dundee.—*Catalogue of Vegetable and Flower Seeds.*
 Thos. S. Ware, Hale Farm Nurseries, Tottenham.—*Catalogue of Choice Flower Seeds.*
 C. Pocock, Wincanton.—*Catalogue of Choice Seeds.*
 W. Atlee Burpee & Co., Philadelphia, U.S.A.—*Catalogue of Farm and Garden Seeds (illustrated).*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (E. M. H.).—Johnson's "British Ferns," published at this office, price 3s. 6d., would interest you, and Hibberd's "Fern Garden," published by Groombridge at the same price, would also be useful. (W. H.).—You might obtain the following works:—Henslow's "Botanical Dictionary," published by Groombridge & Sons, 4s.; Lindley's "Descriptive Botany," published by Bradbury & Co., Bouverie Street, Strand, 1s.; and if you desire a more elaborate work on botany procure Hensley & Masters' "Elementary Course of Botany," published by Van Voorst, London, price 15s. (M. W.).—There is no work published on the subject you name, but full cultural notes have been given, and others will doubtless follow, in our columns. You will find useful information in our Kitchen Garden Manual, which can be had post free from this office in return for 4½d. in stamps.

Cypripedium Leaf Injured (L. T. K.).—Two causes may have contributed to the rusty appearance of the foliage—first, the employment of water containing some injurious substance, and placing the plants in too low a temperature. The former is probably the chief cause, as the injury seems to be confined to the lower portions of the leaf where the water would accumulate in the axils. Rain water is the best, and very little will be needed on

the foliage at this time of year. The temperature should not be less than 55°, and a shady position is preferable for most Cypripediums, as for other Orchids which do not possess pseudo-bulbs.

Garrya elliptica Fruiting (J. S.).—It is rare for *Garrya elliptica* to produce fruit, as it is dioecious—that is, bears the male and female flowers on different plants, and the male plant is the one chiefly grown. Are you sure that your plant is the true *G. elliptica*?

Moving Rhododendrons (J. N., Meath).—No shrubs transplant better than these, and they may be had from a nursery any time from October until the buds commence swelling in the spring. They may be dispatched safely at this season of the year, provided the roots are kept quite moist in transit.

White Cinerarias (G. Snow).—It is not uncommon for white-flowered varieties to be produced from seed, and we have seen many such flowers as those you have sent to us. We do not mean that white varieties are produced from every packet of seed, and we think they are not so numerous as they were some years ago, but they exist nevertheless.

Shallots and Potatoes (J. W., Keighley).—There are no better Shallots than what is known as the small common Shallot and the large Brown. These will keep as long as any so-called "Long Keepers" when the bulbs are well ripened, harvested in good condition, and stored in a cool place. They are sold by nursery and seedsmen, and their price can be found in catalogues. We have not grown "Mackenzie's Pride" Potato; if any of our readers can describe the cropping, keeping, and cooking qualities of this, or McKinlay's Pride, we will readily publish them.

Catalpa Wood (J. H.).—The wood of the Catalpas is very light, but of a pleasing greyish-white colour, and has a fine texture. It requires to be thoroughly seasoned, and is then reputed to be durable, taking a brilliant polish. No doubt you might have many articles of domestic utility constructed from the tree when the wood is properly seasoned.

Coating Hot-water Pipes (Inquirer).—You acted very imprudently in allowing an "oil man" to decide on a matter of this kind. If he had understood the subject he would have known that the fumes of black varnish are injurious to the foliage of tender plants. You have, however, made the best atonement you could by mentioning the evil results that have followed as a "warning to others." To your inquiry "What shall I do?" our advice is, Clean off the varnish with a strong solution of caustic potash, which you can get from your oil man; and if you desire to have the pipes black give them a thin coating of lampblack and linseed oil, heating them gently at first, and they will have a neat appearance, while the plants will be safe. Thanks for your enclosure.

Begonias for Winter (An Old Subscriber).—All the species and varieties may be propagated by cuttings, and may be inserted at any time when a brisk bottom and top heat, say of 75° to 80°, can be maintained. The precise time for insertion must be determined by the size of plants that you desire. If you wish to have large specimens and have heated structures for growing the plants, you may insert the cuttings during February and March. If smaller plants are coveted, May and June will be soon enough for propagating, and a cool frame kept close will be suitable for the plants during the summer. An ordinary mixture of loam, leaf soil, decayed manure, and sand is suitable for growing these plants. The old plants can either be thrown away or repotted after they have flowered. Young plants are usually the most satisfactory.

Culture of Heterocentron roseum (Idem).—Very moderate care will enable you to succeed with this plant, as it both grows and flowers freely in an ordinary stove or warm conservatory. A light compost of turfy loam and peat in equal parts, with sufficient sand to render it porous, is the most suitable, and a small proportion of old well-decayed manure may be added if especially strong plants are desired. The pots must be carefully drained, as abundance of water will be needed during the summer, and when the plants become old and it is not convenient to shift them into larger pots, occasional supplies of weak liquid manure will assist them greatly. The branches may be cut in when they become too straggling, but little attention will be requisite in this respect. It can be increased by cuttings of the young shoots in spring inserted in sandy soil under a bellglass or in a propagating frame.

Culture of Hellebores (H. T. H.).—A deep, fertile, rather strong, yet porous soil is enjoyed by these plants, and a position shaded from the mid-day sun. For choice we prefer a border that is shaded by a wall or distant trees at mid-day. It is important, too, that the roots be not spread out near the surface, but as far as possible they should be made to point directly downwards, the same as Carrots. This hint we had from a person who grew these plants by the acre and sold the flowers in thousands. In growing the plants in pots, place them in a compost of good loam with a little decayed manure and wood ashes added. Plunge the pots over their rims in a partially shaded position in your garden and water the plants liberally during dry weather, giving them weak liquid manure occasionally when they are in full growth. The morning sun and afternoon shade appear to suit them admirably. The foliage should be well sprinkled, and the ground surrounding the plants be made moist during the evenings of sultry days in summer. A good time for dividing and planting is immediately after flowering.

Apple Trees Cankered (J. H.).—We are obliged by your letter and enclosures, which shall have our attention. The question for you to determine is this, Are the insects the cause of the canker or the result of it? This you can determine by experiment. Your theory is not new. As regards hundreds of trees and thousands of cases of canker that we have examined, we are convinced we indicated the cause, and think we have given and can give reliable and practical information, however unsatisfactory it may happen to be in any special case and to any particular individuals. Most welcome, however, will be the results of your researches, as the object of all is the same—the elicitation of truth.

Clerodendron Balfourianum (W. G.).—It would have been better if your plant had only now been going to rest for flowering about the time you mention. Had this been the case we could have told you exactly the time it should be started for flowering when you require it to do so. If the wood is thoroughly ripe, and after the plant has received a good rest, it could be

had in full bloom in ten weeks if grown in a proper stove temperature. If started into growth at this season of the year you might allow a fortnight longer. Keep your plant resting as long as possible, but not in a lower temperature than the one you name, or else it may refuse to start into growth at all. If your plant is in a pot sufficiently large repotting will not be needed; but as soon as the plant shows signs of growth top-dress it with some rich material, but before doing this give the plant a good soaking of water, and remove as much of the surface soil as possible before adding new. After this the trellis should be made secure, and the flowering wood of the plant tied evenly all over it, removing only the unripe ends or dead wood. The plant should after this be placed in a position where the syringe can be employed twice daily, and water administered as may be required, carefully at first until about an inch of wood has been made, when weak stimulants may be given. When the plant naturally starts into growth you must grow it in an intermediate temperature or it will flower too early for you.

Hibiscus sinensis (Idem).—This is a very useful plant for flowering in the stove, but it is not one of the best for growing for purposes of exhibition. You have done right in pruning your plant close in and starting it in brisk heat, as by this means only will you be able to have it in bloom by the time you mention. When your plant has commenced growth potting should be done if needed. Turn the plant out of its pot, removing carefully a portion of the old ball, then place it in the same or a larger pot, using a compost of good fibry loam, a little leaf mould, and about a seventh of decayed manure, with sufficient sand to make the whole porous. After potting plunge in bottom heat, and water carefully until the roots are growing freely in the new compost. The plant should be grown as close to the glass as possible to keep the growths dwarf and sturdy, instead of drawing up tall and weak. It is important if you are to flower this plant profusely that you keep it in as light a position as possible to solidify the growth as it is made. When the shoots have attained a length of 6 inches to 1 foot in length they must be tied out to form the base of the specimen. The strongest may be brought lowest so as to give the weaker ones a chance. If any shoots take the lead of the rest pinch them until your specimen is well furnished with shoots all in the same stage of development.

Determining Angles of Glass Structures (J. W. V.).—The accompanying drawing will enable you to make a very simple instrument—a quadrant,

Fig. 23.

or quarter of a circle, by which the angle of any roof can be at once determined. Fasten a string with a leaden plummet through a hole in the corner opposite the arc or portion of a circle. Divide this arc into 90 equal parts; place the side marked L against the roof inside, and the string will hang opposite to the mark which is the angle of the roof; in the drawing it marks 45°. There is no work published such as you appear to require.

Insects in Mushroom Bed (J. A.).

—We have never before heard of red spider attacking a Mushroom bed, and rarely of wireworms; these, however,

may be in the soil that has been applied. We know of no better remedy than a solution of salt: 2 ozs. of common salt, dissolved in a gallon of water, and applied in a tepid state.

Camellia Buds Dropping (Idem).—Your house has been too warm for Camellias, and the soil has in all probability been allowed to get too dry at the roots of the plant; at any rate the root-action has been defective, and perhaps the air of the house has been too dry.

Peas for Exhibition (J. B. L.).—You omitted to state at what date you require extra fine pods, and no single variety can be relied upon at all times. You as an old exhibitor will admit that it is not wise to rely exclusively upon one variety, unless several successional sowings are made, as so much depends upon circumstances. Perhaps the best Pea for the greater part of the season, or say from the middle of July to the end of September, is Laxton's Evolution. This variety is not much affected by mildew, is very branching, and produces an abundance of long straight deep green pods, which are invariably well filled with fair-sized green peas. The much taller-growing Culverwell's Giant Marrow has larger pale green pods, well filled with very fine peas. It was the most generally shown last season, but the better coloured Evolution will most probably supersede it. By sowing Culverwell's variety in pots and planting out it can be had good near the end of June, and the season of those sown in the open generally extends from the middle of July to the end of August, after that time it mildews badly with us. Evolution under the same treatment is usually a little later. Either Telephone or Telegraph, which differ only in colour, the latter being the greenest, or Stratagem, if a more dwarf variety is preferred, may be relied upon to produce very fine pods, unsurpassed for the early shows, say about the middle of June. To have them early they also require to be planted out, and if sown in the open they are available from the middle or third week of June to the middle of July. Later, unless extra pains are taken, they mildew badly. For the late autumn months, or when Evolution has failed, Ne Plus Ultra and Reading Giant are the best. The latter produces the largest pods, but in other respects much resembles the extremely popular Ne Plus Ultra. All pay for liberal treatment in the shape of well-manured deeply dug ground, frequent supplies of liquid manure, and plenty of room. Overcrowding is one of the greatest evils in Pea culture whether for exhibition or ordinary purposes.

Onion and Carrot Grubs (A. A. T. T.).—It is very difficult to prevent the attacks of the Onion and Carrot maggots in gardens in which these pests abound. The insects pass the winter in a pupa state in the ground, and in this form are so well protected by their cases that it is not easy to destroy them. Ammoniacal liquor from gasworks, and solution of paraffin of the strength of an ounce of oil to a gallon of water, and poured over the ground, are more or less effective and also act as a manure. It is well to have Onion and Carrot beds as far distant as possible from where the crops were last grown and attacked. It is a good plan also to dig the ground deeply a day

or two before sowing, as then many of the pupa cases are placed so far below the surface that the flies cannot readily emerge from them, and thus deposit eggs for producing future crops of maggots. Very heavy dressings of lime and soot are also advisable before sowing. Deep drills drawn and filled with wood ashes, and in these sowing the seed, is a method that has been successfully adopted by some cultivators. Early Carrots sown very late, say in July, grow large enough for use, and often escape the attacks of the pest that ruins crops sown in April.

Sewage Refuse (Vectis).—We cannot tell you even roughly the constituents of the matter "after the liquid portion has flowed into the sea," as so much depends on the filtration; but we are tolerably certain that the best part of the sewage for your purpose is lost. Professor Way has not a high opinion of the manurial value of such deposits as those to which you refer. He regards the solid matter of sewage as "only the woody or fibrous refuse of solid excrement, while ammonia and the more valuable substances were retained in the liquid form. It had been said that the liquid left after the removal of the insoluble portion of the sewage, was 'inodorous, tasteless,' and might be thrown into the river; such a result might fulfil sanitary but not agricultural conditions. No plan was efficient that does not include, in the solid matter obtained, the various salts dissolved in the original liquid. The milk of lime employed in Higgs' process clears the sewage from colour, but leaves in it nearly all the organic matter. London water, too, was hard, already holding carbonate of lime in solution; when quicklime was added, a large precipitate, consisting of double the quantity of chalk, was thrown down, and thus increased, by so much comparatively inert substance, the solid matter obtained, 30 grains of chalk being obtained in this manner from every gallon of sewage liquor. He would prefer separating the sewage matter by itself; but even that would only contain from 2½ to 3 per cent. of ammonia, and would not pay. He recommended farmers to avail themselves of the strongest and best manures, as occasioning less expense in the original cost, carriage, storing, and application. Many methods had been proposed to facilitate the mechanical separation of sewerage matter and to deodorise it; but in all these the valuable salts were left behind. Peat and other charcoal did not arrest ammonia, as had been supposed, but absorbed it as gas by a peculiar power of surface which the charcoal exercised; but water, having a tendency to unite with ammonia, washed this gas out again; charcoal, however, retained the solid matter and deodorised it, but did not separate the soluble salts. Liquid sewerage offered the largest prospect of success, as the whole of the manuring matter was, in that case, utilised." That is the substance of the teachings of an authority entitled to respect. We do not say that other methods of precipitation are similarly unsatisfactory, but we should hesitate to purchase such refuse as that alluded to as a manure for Vines. On this subject we adopt the opinions of an able writer and successful cultivator, that no better plan exists of manuring Vines than utilising sewage and urine; the one contains all the potash, the other the phosphates, and between them everything else plants of any description require. When such can be had no more economical or satisfactory plan can be pursued; all else that is needed is occasionally a little lime and plenty of water. When neither can be had we should employ bones, or, perhaps, better because more economical and likely to be equally efficacious, mineral phosphate, or other cheap phosphate to supply phosphoric acid. Where wood ashes were to be had we would not hesitate to rely on them for furnishing potash, magnesia, and lime. Failing that we would employ kainit, or a cheap source of potash, and apply quicklime sparingly. As for nitrogen, so long as we have sulphate of ammonia or nitrate of soda that need bother none of us. Possibly combination manure might prove more suitable and in the end more cheap. For instance, guano contains plenty of everything except perhaps potash; but it is of little or no use applying manure to Vine borders that do not abound in fibrous roots for absorbing what is given; and where there are no such roots they should be induced in the manner described in the Journal by Mr. Thomson a fortnight ago.

Names of Plants (J. B.).—*Pteris straminea*. (A. G. P.).—*Lonicera Standishi*. (W. H.).—1, *Zygopetalum Mackayi*; 2, *Garrya elliptica*; 3, Resembles *Biota aurea*; 4, *Cupressus macrocarpa*, but it is impossible to determine with accuracy the names of Conifers from such diminutive scraps without any particulars concerning their habit.

COVENT GARDEN MARKET.—FEBRUARY 6TH.

TRADE continues quiet, Grapes scarcely maintaining their value. Cucumbers lower. Kent Cobs stagnant.

THE WELSH BREED OF CATTLE.

(Continued from page 98.)

WE will now notice the observations of another great authority as to the characteristics of the Welsh cattle; we allude to Mr. Thomas Rowlandson, who wrote the prize essays on the farming of North Wales in the *Journal of the Royal Agricultural Society of England* in 1846, and also on the farming of Herefordshire in 1853. We must therefore value his testimony, which has been so amply rewarded by the Council of the Royal Society. He says, when speaking of the Hereford cattle—"All observant persons who have travelled through the county of Hereford and the adjoining district of South Wales as far as Pembroke and the opposite coast of North Devon, must have been struck with the general resemblance in outline of the breeds indigenous to them; indeed the comparison may be carried further, for the Short horns of South Devon and the Sussex cattle greatly resemble the Glamorgans in all but colour, the most esteemed breed of the last-mentioned being black. A mixed black and brown, red and dun-coloured race of cattle, is found throughout all the southern Welsh counties, the whole greatly resembling in symmetrical appearance the true Hereford, varying only in colour."

Although we shall be now obliged to allude to the unprofitable management of various small farmers in certain mountain districts of Wales, this will only be done to give the greater effect in comparison with first-class management, to which we shall allude further on. The cattle bred by these small farmers are found throughout Wales on all the poorest districts, but are reared without much expense or care, and generally kept until they are three or four years old. They are then sold to drovers and dealers, who take them to Barnet and other fairs, such as Blackwater, and there sell them to the Norfolk, Essex, and other graziers, who feed them for the London market. On account of the method of rearing them they are small in size, but pay well when they are fed judiciously in the stalls or boxes on the best managed farms of the eastern and southern counties. These black cattle have ranged in price in the fairs at about three years old from £6 to £9 each, and the four-years old from £8 to £13 each, and are, when made up of prime beef, selling in the London market on account of their good quality and small size at the top prices of the day. About three-fourths of the lots sold at the fairs consist of oxen, and the other one-fourth of heifers. The heifers are seldom spared, but this is a mistake of the farmers who rear them, for it often happens that just as they begin to show the results of good feeding they are found to be in calf, and the high feeding expenses comparatively lost, as the animals would not be appreciated as milking stock.

As we have now shown the various ways in which the Welsh cattle are treated, both for milking purposes and rearing for profit, to be sold for fattening in distant counties of England, we propose to give a notice of a well-written statement which we find in the *Agricultural Gazette* of December 3rd, 1883, contributed by Mr. John Edmunds. He says—"We had heard recently much of the improved condition of Welsh agriculture. We were, we confess, rather dubious, as we had in remembrance some delightful journeys through different parts of the principality which had impressed upon us the idea that there was plenty of room for improvement in this respect. We had, of course, heard of Major Platt's zealous attachment to the movement so recently and so successfully inaugurated or revived, for the maintenance of the valuable, distinctive, and hitherto strangely neglected breed of Welsh black cattle, and we confess that we expected to see something out of the common in the herd of pedigree stock at Madryn Park (Major Platt's farm); but when we found that not only our most sanguine expectations in this respect had been exceeded, we were simply amazed. Madryn Park Farm is to be seen on the left, about midway between Llanfairfechan and Aber stations, on the line of rails between Chester and Holyhead. It is early in the morning, but things have evidently been astir for some time, and there is activity everywhere, under the apt direction and able supervision of Mr David Williams, the Major's farm steward, who is as

proud of the place as Major Platt himself, and to whose care and energy the success in no small measure depends.

Perhaps before we venture into the farmyard we may briefly review the movement now forcing itself rapidly to the fore under the auspices of the North Wales Black Cattle Society, with which Major Platt is so closely identified, and in the success of which he is so much interested. The real origin of the North Wales black cattle seems shrouded in some doubt. The fact was apparent that Wales had a breed of cattle peculiar to itself, cattle hardy as Welsh cattle ought to be, of good constitution, excellent as milk-producers, and, as experience now shows, profitable for exhibition and for the feeder's stall. Mr. Wm. Dew, editor of the "Society's Herd Book," in some interesting introductory remarks, points out how some thirty-five years ago milch cows were selling at from £4 to £7 each. We saw in the herd at Madryn Park a real beauty whose value had been decided by the fall of the auctioneer's hammer, at something not much below £400; it appeared to us likely that even this figure does not anything like represent her appreciable worth to her owner. "A real beauty, a queen indeed," we muttered half aloud when we were leaving the stall. "Yes, when she won the champion prize against all England, there was as much excitement as there was at the election." But this brings us to the rest of the herd of pedigree stock, which now numbers thirty-five head of cattle—all pictures. As we have before intimated, the pick of the cows is probably Black Queen, third, a beautiful beast, standing as square as a table; wide-chested, broad-backed, with tail like a whip lash, and head like a deer. But there are other cows that would satisfy the most fastidious critic, and arouse the admiration of those competent to judge.

The successes of the herd are historical. We may mention the following distinctions:—First prize at Bala, 1881; first prize at Bangor the same year; and in 1882 first at Corwen, Langefin, Towyn, and in the Champion class against all England. The bulls are both large and beautiful. Black Prince, second, now three years old, of the original Beddgelert breed, seems really nothing short of perfection, an opinion endorsed by his attendant, for he looks all loyal as he tells us—"Yes, indeed, sir, as quiet as a lamb, and wins all the prizes wherever he's shown." He moves him away majestically, and Prince Llewellyn fourth, steps into his place, a black prince, and another beauty. The bulls both stand firmly upon their short legs, as square in body as boxes, chests like engine-plates, and hides like silk. The expressive features and quiet demeanour of the faces—if we may use the terms—struck us much, and we approached without fear, and found them as docile as the attendant had said. Here, too, is a beautiful young bull, Rhys. At sixteen months old he has taken the prize in the open Champion class against competitors of all ages. We must hasten on, however. There are two bullocks coming up the yard moving in solemn procession, for a ton of meat cannot move itself swiftly if the means of locomotion are natural and unassisted. These are being brought into condition—one for Birmingham, the other for Smithfield—and are certainly arguments in favour of the North Wales black cattle as meat-producers. Here, too, are young bullocks full of play and power; big frames, upon which the beef will be hung in due time. Here again we have younger stock still, and calves of the present season—pedigree stock, and valuable treasures to perpetuate the reputation of their ancestors—a responsibility they seem quite able to sustain. Leaving the pedigree herd, we come to the stalls, in which forty feeders are leading lives of luxury, in blissful ignorance of the end—for they are intended for the Christmas sale. They are clean and comfortable in their well-kept quarters, and are really noble animals, each a mountain of meat."

We have been induced to close our account of the Welsh cattle with this long quotation, for it is so graphically written, that it is well calculated to leave a lasting impression upon the mind of the home farmer, and also especially upon the memory of young beginners in agriculture and stock-rearing.

WORK ON THE HOME FARM.

Horse Labour.—This has been somewhat hindered by the tempestuous weather which has lately prevailed. It was, however, fortunate that from Christmas up to the 20th of January nothing in respect of the weather occurred to impede the horse labour of the farm, and it has been employed beneficially in completing the fallow-ploughing, chalk-carting, manure-carting on to the Clover seeds, carting of manure and earthy composts on to the dry pastures and park lands. Much threshing of Barley, Oats, and drcge, also of some Wheat has been done, although the latter has in some cases suffered in condition by such early threshing, which is inadvisable, except in those cases where it had been stacked in fine, dry, and first-rate condition. In fine weather threshing corn and pulse crops should be done in order that all the animal power of the farm may be obtained at the busy period of spring to forward the cultivation

for Barley-sowing and other Lent corn, also the preparation of land in readiness for the planting of early Potatoes. We may also anticipate the uses and advantage of a full crop of roots now on the land, especially Swedish Turnips, which may be pulled and heaped on the land if required for folding off with sheep; if not, they may be carted away and stored as food for the cattle in the boxes or for young cattle in the straw yards, and in certain cases for dairy cows. When these roots are allowed to remain in the store heap long enough to throw out little yellow buds they may then be given to dairy cows without imparting any unpleasant flavour to either milk or butter. In the case of a full crop of Swedes being grown, as these roots are so plentiful and the sheep not requiring them all, two-thirds of the crop may be spared for the dairy cows; again, if on a field or fields not required at all for sheep-feeding, and the crop a full one, say of 20 tons per acre, two-thirds of the crop may be chopped and ploughed in, and one-third removed for the cattle on the farm. About 13 tons per acre is quite sufficient to produce a full crop of either Barley, Oats, or drege, according to the soil, taking Barley on the lightest land and Oats on the most loamy soils. In this way the season for sowing will not be delayed, as, though the roots were reserved for sheep-feeding, yet the crop of Lent corn will be superior to that sown after the roots as a whole having been fed off by sheep eating cake and hay in addition. This has been the result of every instance we have seen during the last eleven years. We therefore ask the home farmer, as Swedes may this year not all be wanted for stock, to try the plan we have indicated by ploughing 13 tons per acre of roots against another portion of the field fed off by sheep. This will give him an experience which may prove of great importance in the future as to buying sheep at high prices for the purpose of feeding and folding them on the land. If this plan is pursued with ordinary care, and taking the early part of the season for doing it, he will grow heavy crops of Lent corn without sheep and without losing money on the transaction, as much of this style of farming has done for some years past, if only the value of the food consumed is charged at very small cost for roots, &c., and at the same time saving 40 per cent. of the capital employed on the farm in the outlay for sheep, and also saving 20 per cent. in the labour of attendance upon them, to say nothing about losses from disease, or injury to the land being trodden into mud during the winter months, and seriously impairing the preparation for succeeding crops of Lent corn and Clover.

Hand Labour.—As the weather when open is favourable for the forking-out couch and weeds in the roots or seeds, let it be done by women if possible, otherwise by men, for it really is the best outlay for labour in the dead period of the year, because the couch destroyed by the hand labour done for 5s., would cost 20s. if done further on by horse labour. Showery weather in forking-out is no impediment, but it is adverse to horse labour in fallowing for cleaning the land at any season of the year. Trenching in the meadows should now be done, also constant attention is required in the water meadows by the successive changes of flooding, which it is the business of the drowner to carry out at certain intervals, and unless this is judiciously done the result will not be so beneficial as when regulated by the ordinary rules of irrigation.

Live Stock.—Nearly all varieties of Down breeds of sheep will now have lambs enough fallen, and also old enough to go upon root-feeding in the open field, except, perhaps, certain flocks of Shropshires, Oxford, or Sussex flocks on the hills, where the earliest lambs are not sought for or required. The food for young lambs is very important, for it is usual when reared on the breeding farms for them to run in advance of the ewes and live chiefly upon the greens of the Swedes. In some cases, however, on every tenth drill Rape is grown, which affords foliage of superior quality for young lambs, and just when learning to eat it is of some importance. In the case of the vale farms, where early lambs are required, it is a good plan to have all the roots heaped and a small fold in advance for the young lambs to feed in, without anything except trough food, in which case it is well to give them Carrots or Cabbage passed twice through Gardner's cutter and mixed with the best cake and bean meal; also give cake and corn, either grey peas or beans crushed, in troughs, and the best white Dutch Clover hay in chaff. This is very enticing to lambs by its aroma, for when well made and without Rye Grass of any kind, as we have saved it in some seasons as handsome as a sample of well-saved Hops, and smelling nearly as sweet.

CATCHING MOLES.

THE author of the little book described by your correspondent in page 44 is the true type of professional mole-catchers. They make a great secret of their business, and if questioned they nod and wink in a manner most mysterious. I know how difficult it is to catch a mole if we do not understand the way to set about it, but when once shown the *modus operandi* it is then as easy as "shelling Peas." I will relate briefly my experience. Soon after I left school my father had some marshland much infested with these little vermin. He set me to catch them. I procured some iron traps and went to work. I placed my traps between the hills and in those runs which were just beneath the grass, in which I occasionally caught one. My catches that spring did not average one a week. In June my father gave the bailiff of a neighbouring farm who understood "the trick" a gratuity to teach me. I met him one evening by appointment. He gave me only one lesson; the whole thing was changed, and before the end of that season I had cleared the marshes of the pests.

I will not conclude here as a mole-catcher should, but as I learned from my instructor in one lesson, now invite your correspondent to mentally accompany me on a mole-catching expedition, and I trust when we part he will know enough to soon rid himself of his troublesome little neighbours.

Here we are in a twelve-acre marsh. I have brought with me two or three iron traps, a common walking-stick, and an old sharp butcher's knife. Observe there are molehills in the centre of the field. We will examine

them. They are quite fresh. Here is a grip cut to drain off surface water running by the hills. I guess the mole has come up the grip to this spot. We will follow its course and keep our eyes open. Yes, here is a small quantity of earth thrown out to clear their run. Again another little cast in the grip. It is certain, then, the moles have their run in it; therefore we will follow it to the boundary ditch. We shall now find the run in the bank a little above the water-line. Shall we search to the right or left? We will look round before deciding. Here about three rods to the left and a little distance from the bank are more hills. Then we will search the bank to the left. Now if Nature has given us good eyes they will save trouble. There, look at that bare place on the gently sloping bank. Do you see, about 6 inches above the water-line, the ground looks slightly bulged? We will try with the walking-stick. After slight pressure it has gone through into a hole. With the knife we cut out a piece of earth. It is a main run and quite fresh. Shall we set a trap there? We will look round again, and walk to the second lot of molehills above the bank of the ditch. About 5 rods further up the ditch on the other side are more hills. Most probably the moles which work over the other side cross the ditch and come to this working. (They are excellent swimmers. I once shot one crossing the river Stour. My instructor informed me they continued their runs under ditches, &c. From my own experience I doubt that assertion.) Thence travel the run we have just found up the grip to the first lot of hills. We will therefore walk a rod or two higher up the ditch and search for the run between these three lots of hills. After three or four probings with the stick we discover the run. We cut out a piece of earth, making an aperture sufficiently large to admit a trap. A fine run, 3 inches in diameter, and the marks of their feet as fresh as possible. We will set a trap here, and are certain to catch all the moles frequenting the three workings.

Here is a trap and the iron to set it. We will first pass a string through the hole in the little piece of iron and tie it to the trap. This is a necessary precaution, or there will sometimes be trouble in finding the "setter" after it has been sprung. This trap, not having been used lately, or may be a new one, we will stick the prongs into the soft mud a few times to give it an earthy smell. Hold it carefully by the handles, and before we take hold of the setting iron we will make our fingers muddy. We set it so that a touch will spring it. Place it gently in the run. Be careful never to put your hands into the run. (I believe the sense of smelling is very keen in moles). If you are careless of this, you will find the moles will work round or under instead of going through your trap. Cut two pieces of turf to lay over the trap, making it snug, leaving only the handles visible, over which, to prevent your trap being either stolen or disturbed, throw a handful of long grass.

Before we part come with me to another working, which I have visited before. The hills were rather old, and the run to them had some grass growing in it. I did not set a trap, but stamped the run down by drawing my foot across it. Here is the place and there the mark of my foot as I left it. If a mole had come along the footmark would have been heaved again, therefore it will be useless to set a trap here.

The following extract is from the "Sportsman's Directory," by John Mayer, game-keeper:—"The mole is in some places, but more particularly in the north of England, called a wunt, and, contrary to most other vermin, lives chiefly underground, and does great mischief in gardens, &c. When you find they come, observe the outsiders for their angle or run; or, if there is a path in a field, it is very probable that they have a run across it, or they will frequently have one at a gateway. These are what are called the main runs, about 2 or 3 inches under the earth, and may easily be found by the heaving up of the earth, along which they will run ten times in a day. When you have discovered one of these runs you must tread in the earth tight, and when you come that way again see whether it is as you left it; and if you perceive a mole has been along, then set a trap, by which means several may be caught in an afternoon, these being their main roads out of one part of the ground to the other, for it will be of little use to set a trap in any other angles or runs. In spring, when they run near the surface of the earth, they make many different angles in search of worms, on which and chaffers they chiefly feed.

"In the spring, when you catch a she mole, rub her back part about the bows of the traps. Observe, when you have caught all that you perceive to move, you need only look round the outside of your fields, and keep some traps constantly going there, and they will lay hold of them as they come in and out. If you put some dead moles in the runs it will prevent their coming and keep your grounds free from these troublesome vermin."—EDWARD HARNETT, *Minster*.

REMARKS.

27th.—Windy during night; slight snow shower at 10.30 A.M., then fair; lightning at 10.30 P.M.
28th.—Fine throughout; clear sunset, but little special colour.
29th.—Foggy in morning, then became very warm and fine.
30th.—Very close, with rain and wind.
31st.—Heavy rain in night, and raining nearly all day.
1st.—Fine morning; wet and wild in afternoon; fine evening.
2nd.—Overcast early, but nearly cloudless after 11 A.M.
Rather a wild and wet week. Temperature still above the average. During the whole of January the air never fell to freezing point—a very unusual fact.—G. J. SYMONS.

OPEN-AIR FIG CULTURE.

FIGS as grown and ripened in this country without the assistance of glass cannot by any means be termed popular. Yet they are decidedly wholesome, and if not exactly delicious as we generally understand the word, are at any rate fully appreciated by those who have acquired a taste for them. I include myself in this category, and my liking for them dates from the commencement of my gardening career. I first tasted fruit of the White Marseilles, and if more of this delicious sort were grown in the open air we should hear fewer remarks that English-grown Figs are generally "insipid" or "positively unpleasant." It must be conceded that Figs ripened in the open air of this country are much inferior in quality to house-grown fruit, neither is this to be wondered at, seeing they are natives of a far drier and hotter clime than ours. At the same time, if we cannot grow them to perfection in our variable climate, there are many districts where they may be and are most successfully cultivated, the fruits thus obtained being very acceptable and even profitable to the cultivators.

The southern counties of England appear to be most congenial to Figs, and in Kent and Sussex, especially along the coast and indeed for about twenty miles inland, they, to my knowledge, thrive admirably, while the Isle of Wight has long been noted for fine Fig trees. The neighbourhood of Bristol, again, suits them well, and this further convinces me that the sea breezes are favourable to their culture. Sea breezes alone, however, are not sufficient to insure success, and, it may be, quite as much depends upon the nature of the soil in which they are planted. In nearly every case where I had an opportunity of looking into the matter, notable examples of Fig trees were growing in soil in which either chalk or lime rubbish was freely incorporated. The finest trees I have seen were grown almost immediately below the Shakespeare Cliff, near Dover, and in very chalky soil which prevails and was brought in baskets from the top of the extensive cliffs thereabouts. The trees owned by a fisherman in charge of a stretch of land and beach at the base of the cliffs, were roughly trained up high concrete walls built to support the railway between two tunnels. These remarkable trees formed the most sturdy short-jointed and therefore fruitful growth imaginable, and the annual crops of extra fine fruits realised high prices, or 4*d.* each on an average, at Dover and the Covent Garden Market. No other kind of fruit tried succeeded in this position. Some time since I found on inquiry that unusually high seas about four years ago killed the Fig trees and completely ruined a small piece of land that had been invaluable to the man in charge for the production of crops of early Potatoes. The sea had once previously laid bare the roots, thereby greatly damaging the trees.

Another grand specimen of Brown Turkey Fig, at one time growing at the end of a gentleman's stables not far

from the Sussex coast town of Rye, was rooted principally in a very chalky border especially prepared for it. As affording an instance of the Fig's superior tenacity of life as well as its evident capability of storing sap, I may mention that the stem of this tree was at one time intended, if not actually used, for a walking-stick. The gardener, an old friend of mine, who cut it after the foliage had fallen, left it unnoticed in his kitchen during the winter, and in the spring it was found to be pushing its buds. By way of an experiment it was taken back to the garden and fixed in good soil at the base of a warm wall, where it rooted and eventually became a large and most prolific tree. In the same garden a good-sized standard Fig tree rarely failed to perfect good crops of fine fruit, and at one time, though I did not see any when there, there were numbers of standard Fig trees growing about the Isle of Wight. As a rule the Fig is not hardy enough to be grown as a standard and requires the shelter of sunny walls.

To treat them similarly to either Pear or Peach trees, as they very frequently are, will in most cases prove a great mistake, as if encouraged to grow at all luxuriantly they are neither hardy nor fruitful. They require a well-drained border and a compost consisting of equal parts of pure loam and either chalk or lime-rubbish. Into this they root at an extraordinary rate, but unlike richer soils it is very conducive to short-jointed hard growth, and that attained half the battle is won. First get your proper fruiting wood, and then feed the trees exactly as Mr. D. Thomson so successfully treats the roots of his Grape Vines, and which he very plainly described on page 58. In common with the Grape Vine the roots of the Figs require plenty of moisture, and this is best assured by their being heavily mulched with good rough manure in the summer, and in addition, if the summer prove exceptionally dry, a few good soakings of water should also be given. A liberal top-dressing of loam, manure, and chalk or lime rubbish to be forked in during the autumn or winter, and no surface crops of vegetables to be taken from the border, these tending to rob the Fig trees and to cause a tendency to deep root-action, and consequently unfertile wood.

The hottest positions on the walls of a garden should be assigned to the trees, angles formed by a junction, east and south walls, being particularly favourable. Even there, in most localities, they will require protection during the winter. The roots should be protected with a mulching of long strawy stable manure or other light material, while the whole of the stems and branches may be preserved either with mats or freshly cut and closely fixed branches of Spruce or other Firs. The less pruning a well-established tree receives the better; but it is necessary to occasionally cut hard back a few large branches at different parts of the tree, the young growths resulting furnishing the centre, which otherwise would in most cases become bare. A tree with a clear stem is best, as less liable to produce suckers, which if encouraged are usually a long time very succulent and unfruitful. There are a few who stop the young growths during the summer, but no greater mistake could generally be made, as it is near the points of these where the embryo fruits are formed during the winter. Very rarely do the small fruits near the size of Gooseberries, which remain on when the leaves have fallen, survive the winter and attain maturity, and it is to the points we must look for a more certain if later crop. Disbudding, however, should be practised where the shoots give signs of being too thick.

The variety most preferred for the open walls is the Brown Turkey, this proving hardy, prolific, and of good quality. Brunswick is more luxuriant, consequently less fruitful, but the fruits are large, handsome, and good in quality. The smaller White Marseilles is the most delicious, but out of Kent and Sussex I have not met with it, and therefore suppose it is not much grown. Brown Ischia is also well adapted for open-air culture, and I much like the

quality of its rather small roots. Here Fig trees do not long escape damage by frosts, and a good house has done away with the necessity of so much care being expended over them. In less moist localities I should have no fear of failure in the open air, and should take every pleasure in their cultivation.—W. IGGULDEN, *Marston*.

EXPERIMENTS IN POTATO CULTURE.

In your issue of July 5th, when you kindly favoured us with advice on the subject of manuring Potatoes, you were also good enough to interest yourself in our proceedings and to express a wish to hear of the result. This I should have given before now but that my notes thereon were all in the rough, and I have been too much occupied until quite lately to get them into proper order. Before going further I will avail myself of this opportunity to thank you most heartily for the kind advice you have given me from time to time, advice to which I attribute the greater part of our success.

By the time your answer to my query reached my hands I was absent in Brittany, and, time pressing, my partner had already applied the mixture which I had suggested—viz., $1\frac{1}{2}$ cwt. nitrate of soda and 1 cwt. nitrate of potash per acre. I may here mention that the whole of the ground had been trenched two spades deep, and had received a liberal application of lime, ordinary superphosphate, and compost. This season I hope to try over half of our ground the mixture you recommended—viz., $\frac{1}{2}$ cwt. nitrate of soda, $\frac{1}{2}$ cwt. potassic chloride, and $\frac{3}{4}$ cwt. superphosphate.

The Sologne, in which our work lies, is not by any means a favoured district either as regards its soil or climate. The former, as a rule, consists of large tracts of black, sour, sterile Heather soil, varied here and there with patches of stiff, cold, unworkable clay. Sometimes a spit deep of the heath soil overlies the bed of clay, and when the two are worked up together forms about the most favourable compound we have to deal with. The climate, too, is very unreliable—subject to great extremes of heat and cold, of drought, and where undrained of saturation.

Of the land we put under Potatoes about half the total extent (say three-quarters of an acre) consisted of meadow land—such as meadows are in these parts—and had been planted up with Asparagus on the Argenteuil system. This was perhaps the most suitable soil we had for the purpose. The Potatoes (Royal Ashleaf and Magnum Bonum) were planted in the ridges between the lines of Asparagus, and in the case of the latter gave a most satisfactory return.

The remaining ground, of about the same extent, consisted equally of two totally different soils, one-half being a stiff cold clay, in which we grew Myatt's Ashleaf, Schoolmaster, Snowflake, and the French variety Saucisse with moderate success; and the remainder, which was all sandy heath soil, was planted with Bresee's Prolific, International, Adirondack, Queen of the Valley, Reading Russet, Paterson's Victoria, and Scotch Champion. From some of these the best results were obtained. The chief object of putting the ground under Potatoes was to render it fit for use as forest nursery this coming season, and, unless appearances are very deceptive, we have fully succeeded in our object. On the whole, the variety rather than the nature of the soil seems to have effected the results.

It will be observed that we cultivated a single French variety—viz., the Saucisse Rouge, which has a considerable reputation in this country, owing solely, I fancy, to a want of knowledge of better varieties. It is a large, coarse, hard, yellow Potato of bad quality, subject to disease, and has not even the merit of being a heavy cropper.

The following table will show the quantities planted of each variety and the yield obtained, and its per-centage in the seed put down.

		YIELD.	
	cwt. lbs.		Per-cent.
2 cwt. Royal Ashleaf.....	20 0	10.00
2 „ Magnum Bonum.....	60 0	30.00
1 „ Snowflake.....	9 28	9.28
1 „ Bresee's Prolific.....	10 20	10.20
1 „ Myatt's Ashleaf.....	10 0	10.00
1 „ Saucisse.....	10 46	10.41
53 lbs. Schoolmaster.....	8 28	16.50
14 „ Scotch Champion.....	2 92	22.57
11 „ Paterson's Victoria.....	1 88	14.28
14 „ Queen of the Valley.....	2 93	23.00
14 „ Mona's Pride.....	1 16	9.43
7 „ Reading Russet.....	1 42	22.00
7 „ International.....	2 0	32.00

The return of Magnum Bonum, Royal Ashleaf, and Myatt's

Ashleaf I have been obliged in part to give my estimate, but I believe I am well within the mark.

The most satisfactory result that I have to note in connection with our experiment is that out of the whole crop above mentioned (save Saucisse) I have only been able to find up to this date one small diseased tuber, and that occurred among the Schoolmaster. It is possible that even this was a tuber of Saucisse that had found its way in by accident. Magnum Bonum has proved a little coarse in flavour, but all the rest are as excellent in quality as could be desired.

In this district the Potato crop is a most important one, and by the introduction of new and improved varieties the return might not only, I am convinced, be at least doubled but also its value greatly enhanced. This season our hope is to give our experiment considerable extension, not only in the extent under cultivation but also by adding several new varieties to our list, and I trust we may in time see some improvement in the Potato cultivation of this district.

These notes have already by far exceeded the limits I had intended to assign to them, therefore I must not let my ardour on the subject carry me away at greater length.—E. J. C. B., *Loire et Cher*.

CACTACEOUS PLANTS.

GENERAL CULTURE.

(Continued from page 86.)

Temperature.—Where a large and mixed collection of Cacti is grown in one house, species from widely differing positions and climates have to submit to a uniform system of culture as regards temperature; but this, it appears, is not a particular disadvantage, for if a few general rules are observed these plants will thrive under any reasonable treatment. The delicate Mamillarias, the robust Cereuses, and the most tropical of the Echinocactuses can be grown together in a house to which no heat is applied during the winter except to exclude frost, but then they should be kept very dry and must be placed in warmer quarters in the spring to start them into growth. I know an extensive collection which has been so treated for some years with good results, but they are under the care of an experienced cultivator who has devoted a life to the study of their peculiarities, and anyone who is not familiar with such plants would act unwisely in testing them so severely. The safest winter minimum temperature is 50° to 55° for all the tropical species, the half-hardy, and in wet districts even the hardy sorts, being preferably wintered in a frame where they can be protected from frost. From March onwards the temperature may be raised to 70° to 80°, while with sun heat it may be increased to 90°. In the height of summer, by which time the growth of the majority of the species will be completed, the house or frame must be fully ventilated, and no shade will be required. A free exposure to the sun is as requisite to consolidate the growth of these plants as in the case of most fruit trees. In the autumn the temperature may be gradually reduced as the external heat diminishes, 60° to 65° by day, and 50° to 55° at night, suiting all the family.

Soil.—It is a general idea that for these plants a special and elaborate compost is absolutely indispensable, yet they can all be satisfactorily grown in ordinary loam and sand provided the latter be added in sufficient proportion to render the whole thoroughly porous, and there is no doubt whatever that the conventional lime rubbish is often employed in quantities that are positively injurious. In the case of delicate plants the pieces of broken bricks used may occasionally have a bad effect by attracting and retaining the moisture near the roots, and the lime in excess has a tendency to diminish the porousness of the soil. A small proportion of lime should, however, be employed for the Cereus and Opuntia type, as these secrete crystals of oxalate of lime in large quantities, and it is also advisable to add some finely broken bricks when the loam is inclined to be heavy. Indeed for all the strong-growing Cacti such material may be preferably employed, as it enables the cultivator to supply water more freely and safely than would otherwise be the case. The pots must be carefully drained, as this is a matter of much importance. From one-fourth to one-half the depth of the pot should be filled with draining materials, according to the size and condition of the plants which mostly require but little soil.

Water.—Under the cool system already mentioned very little water is needed for at least three months in the year—namely, November, December, and January, though when in pots the plants should be examined once a week. Some growers, however, especially those in the trade, turn the plants out of the pots at the commencement of winter, shake the soil from their roots, and lay them upon dry sandy soil, where they remain without the smallest supply of water until it is desired to start them in spring, when they are planted out in a frame to make their growth, being syringed and watered freely. In the ordinary Cactus house, which is kept at a rather higher temperature, water is needed more frequently even in winter, but some experience is required to determine the proper time to apply it. The soil must never be allowed to get in a stagnant saturated condition, or the strongest plants will soon die, and it is often more easy to judge by the appearance of the plant whether moisture should be supplied. If the whole tissue seems to be plump and full none is needed, but if there is the slightest approach to laxness, or a dullness in the surface colour, water should be given. In the spring and early summer, when growth is advancing, whether the plants are in a house or frame, slight syringing in the afternoon is very beneficial, particularly after potting, and it will not be necessary to apply water direct

to the soil for a week or so after that operation, as the syringe will afford sufficient moisture. When growth is proceeding rapidly the plants may be watered twice or three times a week. The stronger freely flowering species of *Cereus* and others may be assisted with a little weak liquid manure, both when growing and approaching the flowering stage.

Potting.—February and March is a suitable time for potting Cacti, and if the collection is large the earlier the operation is performed the better, provided the weather is open and mild. Some care is needed in obtaining the soil in proper condition, for it should neither be damp nor dust dry, but it is better to err on the dry side than in the other direction. When the plants are turned out of their pots most of the old soil may be shaken from the roots, and all dead dried roots must be cut off close to the stem, as much injury is often occasioned by allowing these old portions to remain attached. Large specimens in tubs or pots of considerable size seldom need repotting, a top-dressing of fresh compost, with occasional supplies of weak liquid manure, being amply sufficient.

PROPAGATION.

The majority of the Cacti are readily increased by cuttings, grafting, and by seeds, each of which methods may be briefly described.

Cuttings.—The species of *Cereus*, *Opuntia*, *Rhipsalis*, *Epiphyllums*, and others with cylindrical or slender angular stems, can be increased by means of cuttings of the young growths, which may be taken off in the spring and summer and placed in a sunny position for a few days, until the cut surface has healed, or until a few roots are seen to be forming. They can then be inserted in pots of light sandy soil, and kept quite dry until growth commences, when slight syringing will be beneficial. The temperature of the house in which the plants are grown will be sufficient. The *Mamillarias* and some of the *Echinocactuses* and *Echinopsis* produce a number of offsets from the base of the stems, which may be removed and treated like cuttings, and a large stock can be soon obtained of many species in this way.

Grafting.—The principal object of grafting in this family is to place delicate species upon stocks of a stronger character, so that there is less danger of the former suffering from superfluous moisture in the soil, as with some *Mamillarias*, or to elevate pendulous or drooping plants upon a stem, so that they can be seen to better advantage, as in the case of the *Epiphyllums*. Some of the slender *Cereuses* seem to be benefited by being grafted on stronger stocks both in their growth and floriferousness, but the latter character is usually not much affected. There is one great objection to grafted plants, and that is that usually they have an incongruous appearance almost approaching to deformity, and on this account many growers do not practise it. The operation is generally performed in early summer when growth is proceeding, and the methods employed are extremely simple. The stock, which is usually one of the *Cereuses*, such as *C. tortuosus*, *C. macrogonus*, or *C. peruvianus*, according to the habit of the plant from which the scion is to be taken, the second-named being one of the quickest growing of all, or the *Pereskia aculeata*; but this is principally reserved for the *Epiphyllums*. If one of the small globular *Mamillarias*, *Echinocactus*, *Echinocereus*, or *Echinopsis* is to be the scion the base should be cut smoothly across, and if the stock is a sufficiently broad stem this can be similarly smoothed and the scion placed level upon it, being secured in its place by matting or string passed over the plant and under the pot, so as to keep the cut surfaces in close contact. No binding is required round the junction of the stock and scion, and if the plants are placed in a rather shady position for a few days and kept dry a union will soon be effected. When the scion and stock are slender, and if nearly equal in size, they may be grafted by cutting the former at the base into a wedge shape, with a corresponding notch in the latter, tying them carefully round in this case, but not too tightly, or the surface will be injured, and probably decay. Nearly all the species in the different genera of the Cactus order unite readily with each other, but it is not well to select a plant for a stock which differs greatly in quickness of growth from the scion or *vice versa*, for the success of the union is very uncertain in such cases.

Seeds.—Though the majority can be easily raised from seeds, this method is rarely resorted to except to obtain new varieties or hybrids. The seeds are mostly small, and should be sown in a compost of three parts sand and one of loam in a temperature of 60° to 65°. The best time is immediately the seeds are ripe, otherwise the spring months are the most suitable. Germination takes place in from one to three weeks, and the progress of the seedlings is often very slow for some months, during which time the greatest care must be exercised to prevent injury by too much moisture either in the soil or the atmosphere.

Hybridising.—Nearly all Cactaceous plants produce abundance of pollen, and are readily crossed, especially the *Cereuses*, *Phyllocactuses*, and *Epiphyllums*, to which the efforts of hybridisers have been principally confined. By judicious crossing some handsome forms have been raised, and there is undoubtedly plenty of room for further experiments in this direction. For instance, the *Mamillarias* vary considerably from seed, yet very little has been done in this genus on any systematic plan. In the majority of species the pollen and stigmas are mature at the same time, and therefore if self-fertilisation is not desired the stamens of the flower selected for the seed-parent must be removed before the anthers burst; and if there are other flowers open at the same time a small piece of gauze or muslin may be tied over it both before and after the pollen is applied. The *Cereuses* hybridise readily, and it is only necessary to observe closely the time when the flowers open, as some last but a few hours, often expanding late in the evening.

CLASSIFICATION.

A great number of methods of classifying the members of this

family have been proposed, but that adopted by Hooker and Bentham in their "Genera Plantarum" is the simplest and best. Two tribes are formed. The first, termed *Echinocactæ*, is characterised by the calyx tube being produced beyond the ovary, the stem being covered with elongated tubercles or ribs, which are rarely leafy. This includes the genera *Melocactus*, *Mamillaria*, *Pelecypora*, *Leuchtenbergia*, *Echinocactus*, *Discocactus*, and *Cereus*. The second tribe, *Opuntiæ*, has the calyx tube not produced beyond the ovary, and the stems are branching or jointed. The genera *Rhipsalis*, *Nopalea*, *Opuntia*, and *Pereskia* are placed under this head. Some secondary divisions are adopted, but they are not of much popular importance. In classifying the species the spines afford valuable characters, and those who are specially interested in this part of the subject will find an elaborate system detailed in Labouret's "Monographie."

MELOCACTUS, Link and Otto.

(The Melon Cactus.)

About thirty species of plants found in the West Indies and tropical America are arranged under the genus *Melocactus*, and resemble each other closely in their leading characters. These are a globular un-

Fig. 24.—*Melocactus communis*.

branched fleshy stem 1 to 2 or 3 feet in diameter, regularly ribbed from base to summit, the ridges bearing a varying number of clusters of spines and a cylindrical portion, termed "the cap," produced from the apex of the stem, formed of a woolly substance, and closely set softer spines than those on the main stem. Upon this the small flowers are borne, tubular in form, and red or rose-coloured. All the species are natives of hot regions, generally growing in rocky or sandy situations exceedingly dry, but a few are said to be found near the coast or in salt marsh districts. Only one species—namely, *M. communis*, is in general cultivation, and this is probably owing to the fact that the plants are of little or no horticultural value, though as curiosities they are remarkable.

Culture.—The *Melocactus* is one of the most difficult of all the Cacti to grow successfully, and it is rare that a thoroughly healthy specimen is seen; indeed, imported plants that have "the cap" developed when received seldom live long, and the only specimens which have a chance of success are those sent over in a young state or raised from seed here. A high temperature, very porous soil, abundant drainage, and little water are the chief points requiring attention, and when a plant assumes an unhealthy appearance water must be withheld.

Propagation.—Offsets are seldom produced unless the crown or cap be removed or damaged, or if the upper portion of the stem be cut off. When the surface is partially healed offsets usually appear round the margins, and these can be separated and grown on like those of other Cacti.

MELOCACTUS COMMUNIS, *Link and Otto*.—"Who can but marvel at the care and singular workmanship shown in this Thistle?" wrote old Gerard in his "Herball," 250 years ago, and the question might be repeated at the present day with equal point. It is, indeed, much more peculiar than beautiful, but it is interesting historically as one of the earliest known members of the family. Most of the early English writers on plants notice it, and the author named above gives a particularly good engraving, showing the cap and spines very clearly. He terms it *Melocardus Echinatus*, the Hedgehog Thistle, and says concerning it, "This admirable Thistle groweth upon the cliffs and gravelly grounds neere unto the sea side in the islands of the West Indies, called St. Margarets and St. John's Isle, neere unto Puerto Rico, and other places in these countries, by the relation of divers travellers that have journeyed into these parts who have brought me the plant itself with his seed, the which would not grow in my garden by reason of the coldness of the climate." It was thus introduced early in the seventeenth century, but some time elapsed before it was generally known. Parkinson described it in his "Theater of Plantae," 1640, as "*Melocardus Americanus*," and gives a figure very similar to Gerard's. Ray also fully describes it in his "Historia Plantarum," 1686, and states that it was then cultivated by Bishop Compton at Fulham. In Bradley's "Works of Nature," 1739, a small figure is given, and he mentions having seen specimens in the Royal Gardens, Hampton Court, and in the Physic Garden at Amsterdam. Miller grew plants of the species and several varieties at Chelsea, and it was included in the Kew collection of 1811.

Turk's Cap, Englishman's Head, and Pope's Head are some of the popular names that have been applied to this plant, all referring to the peculiar crown on the summit of the stem, a character by which it is easily recognised. It is found in several of the West Indian Islands, particularly on the island of St. Kitts, where it grows in large quantities in barren rocky districts. It is also found on the mainland, and specimens exceeding a yard in diameter are not uncommon, some being reputed to be two or three hundred years old. In places where it abounds the mules and other cattle are said to eat the plants after removing the spiny outer portion with their hoofs, as the fleshy substance of the stem affords a welcome supply of moisture. As grown in this country, the stems are from 12 to 18 inches high and about a foot in diameter, with from twelve to twenty ridges 1 inch to 1½ inch deep, conical in shape, and bearing clusters of eight or nine spines quarter to 1 inch long, the centre one being erect, and the clusters an inch apart. The flowers are about 1 inch long, large tubular, and rosy red, somewhat suggestive of some of the small-flowered Fuchsias; these are followed by red oblong fruits resembling those of the *Mamillarias*.

The seeds are small, and in germinating produce two very minute cotyledons at the base of a globular fleshy stem. These have been overlooked by some botanists, and the plant regarded as a monocotyledon. In Decaudolle's "Vegetable Organography" a figure is given showing the true form of a young seedling with the diminutive cotyledons at the base of the plumule or gemule.

Numerous varieties have been named and described, such as *macrocephalus*, *oblongus*, *conicus*, *acicularis*, *spinosior*, *magnisulcatus*, and others, the names of which indicate the leading characters, but seedlings seem to vary so much that these names are not of much value.

The engraving (fig. 24) is a reduced representation of a plant of *M. communis*, showing one of the conical type, and one-sixth the natural size; a flower is also given of the full size.—LEWIS CASTLE.

(To be continued.)

DEATH OF MR. ALEXANDER HONEYMAN.

OUR readers will be prepared for the event that it is our melancholy duty to announce—namely, the death of our talented correspondent "Single-handed," which occurred after a painful illness on Sunday last at West Brighton, Sussex. On a future occasion we hope to publish a portrait of this estimable man, and give some particulars of his career; at present we insert the following letter, by his especial wish and in his exact words—his last words to ourselves and our readers. It is a noble yet pathetic communication that would be weakened by any comment at the present time.

A LONG FAREWELL.

"SINGLE-HANDED'S" LAST COMMUNICATION TO THE EDITORS AND READERS OF THE JOURNAL OF HORTICULTURE.

DYING!—for his medical advisers tell him his last chance has failed. It is hard. Only thirty-three. Life only beginning. My sun just rising. Doors of usefulness opening everywhere—radiant promises beaming, when the King comes!

I had hoped and worked to be second to no practical man in Britain, and the first in science. I had hoped to revolutionise gardening in the coming years, and on a scientific base to move it up. But for me the fight is ended. It is hard; but I have all along been used to hardness, and can lay down my begun work even with a smile at the vanity of human things.

But one thing no philosophy can help me in. There nothing can temper the grief that consumes me, and that is leaving penniless, helpless, a poor wife and five little ones. Oh, my pets! my bairns! Five hundred miles from friends, and all I had saved for them swallowed in my year-and-a-half's illness and idleness. I can write no more: strength fails: reason swims. Farewell for ever!

In reference to the last paragraph, Mr. Wright desires to add that by the responses of generous hearts he hopes to meet the immediate and pressing wants of the bereaved family. He has received several sums during the week, which he has acknowledged privately where addresses were given, and a valued contribution of £2 3s. is announced through Mr. Bardney from the Committee of the Liverpool Horticultural Association, which calls for public acknowledgment. "A Stranger," "W. B., Rothbury," and a "Working Gardener," are also thanked for their aid. In accordance with the wishes of many who have helped, a subscription list will not be published, but the amount raised and handed to Mrs. Honeyman will be announced in the course of a week

or two, and in the meantime Mr. Wright will take charge of any further sums that may arrive at our office.

The remains of Mr. Honeyman will be interred at 2.30 this day (Thursday) at the Hove New Cemetery, Brighton.

CULTURE OF THE BOUVARDIA.

THE *Bouvardia* is one of the most useful winter-blooming plants we have, for the same specimens may be kept continually in flower from October till April, as the plants can be brought on in two or three batches. After the plants have flowered they are placed in a lower temperature and gradually dried so as to give them a thorough rest. They should then be cut back to the ripened wood and placed in heat. If they are syringed once or twice a day they will soon commence growing vigorously, and cuttings may be taken, but not with a heel of the old wood attached; only use the young soft growths, inserting them in well-drained pots. The soil should consist of two parts of leaf soil, one of loam, with a liberal addition of silver sand, and half an inch depth of this latter on the surface. After the cuttings are inserted give a thorough watering and place them in a close propagating frame, where they will soon root if properly attended to as regards shading and moisture. After they have rooted and grown a little pinch out the points, and when they have started again place them singly in small pots, using the same soil as the above. Keep the plants in the same house until established, when they may be removed to one of an intermediate temperature and grown steadily on, pinching out the points as required to make them bushy. They should not be allowed to become root-bound before repotting, which should be this time into 48-size pots. The soil may then consist of two parts fibry loam, one of leaf soil, and one of well-decayed cow manure, with a liberal addition of sand.

At the commencement of June place the plants in a cool frame, removing the lights on warm nights to gain the benefit of the dews and warm showers. The stopping should be regulated according to the time they are required in bloom. After the plants have filled the pots with roots a few may be repotted if large specimens are required, and the rest supplied with weak liquid manure, Clay's fertiliser, or Standen's manure, shading them slightly during very bright and hot weather. It is a great mistake to allow them to remain in the frame too long. By the first or second week in September they should be transferred to a house, and at the end of the month a batch may be introduced into an intermediate temperature for early blooming. The others can be placed in heat as required, but the temperature for the later batches should not be allowed to fall below 50°. Some recommend planting *Bouvardias* out in the open air and in frames, but I think the system has little to recommend it. As regards varieties, those of the *Vreelandii* type are the most useful, but Bridal Wreath and *jasminoides* are not to be despised, or the new doubles. Some prefer *Humboldti corymbiflora*, being the largest flower, but if this is grown it must not be pinched late, or the result will be few or no flowers.—A. YOUNG.

MIXING PETROLEUM WITH WATER.

It may not be generally known that petroleum may be used as an insecticide rendered soluble in water to any degree of strength required by a very simple process, it merely being necessary to expose Gishurst compound previously cut into fine slices, and petroleum separately to the action of several degrees of frost for a few hours, and then pouring the oil on the compound and stirring vigorously; the oil will cause a vapour to arise, in fact to melt the Gishurst while in a frozen state. I herewith send you a sample of the compound and oil, united in the manner above described twelve months ago. I have kept it so long to ascertain if the oil would revert to its former state, but you will perceive that the blend is a fixed one, and that boiling water has merely to be poured on from 1 to 4 ozs. to obtain what I know from experience to be one of the most efficient and cheapest insecticides known. I find it certain death to all insects it comes in contact with, while harmless to the most tender foliage, and the oil being equally distributed and held in solution by the Gishurst, the advantages of the united and well-known excellence of both can well be imagined.

As a winter dressing for Vines, Peach, and other trees Gishurst has few rivals, and petroleum none. The difficulty with the latter has been to trust its use to a careless or indifferent person. In careful hands warm soapsuds answered very well, but still the danger remained, but now with the aid of our friend a child may be trusted to use it to any extent or for any purpose.

I have sent this method of uniting the two insecticides to the manufacturers of Gishurst compound, as I hope they will prepare it and introduce it in different strengths for different purposes, as it will

not be always convenient for gardeners or amateurs to make it themselves, unless they could employ ice or take advantage of a night's frost. Anyone with the aid of plenty of ice or chemicals could freeze enough in a few hours to last for years. Gishurst must be employed, no other will do, and it must be borne in mind that as more oil cannot be added, several strengths must be made. I shall be happy to give any further information if required. — J. WOODWARD, *Ardgillan Castle Gardens, Balbriggan.*

[The mixture referred to appears complete and satisfactory.]

THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE eighteenth annual meeting of this excellent and admirably conducted Society was held on Monday night at the Caledonian Hotel, Adelphi, London, Mr. Richard Dean, one of the honorary members, ably presiding. The large room was crowded by an assemblage of the most respectable men in the gardening ranks, and the close attention they gave to the business of the evening, and the manner in which everything was conducted, indicated equally the intelligence of the men and their undoubted business aptitude. There are not a few gardeners who object to meetings of this kind being held in a public-house. It may be well to say, therefore, that a private room in a large London hotel is for the purposes of a meeting exactly similar to a room in a private residence or a temperance class-room, as those members present wearing the blue ribbon can readily testify. That point being made clear, we will briefly refer to the business of the meeting.

After the election of a number of members the report was read by the Secretary. This was in every respect except one the most gratifying that had been prepared on any previous occasion. It showed a far greater increase of members than during any preceding year, also greater additions to the benefit, benevolent, and management funds; but the demands for sickness had also been greater than usual. This at once shows the great usefulness of the Society, and its safe, sound, and firmly established character. During this year of what may be termed "great sickness" the sum of £9 19s. 6d. was paid in benefits, amounting to 2s. 6½d. per member; but against this, and without taking into account any contributions at all, there arose as interest from the moneys invested in consols the sum of £45. If we add to this the subscriptions of members, £163, not another word or figure is needed to show the thoroughly substantial character of the Society. The balance in hand on account of the benefit fund is £1699 7s. 7½d., or an increase during the year of £194 11s. 1¼d. The balance on account of the benevolent fund is £909 11s. 0½d., or an increase of £52 19s. 7¾d., the balance in the management fund being £5 4s. 5d. against £3 8s. 10d. last year. The total accumulated fund now invested in the Bank of England and credited as the Society's stock is £2699 12s. 6d., as certified by the Auditors of the Society, Messrs. A. J. Green and J. D. Dick.

It is in the appropriation of this ever-increasing funded property that this Society differs from all other organisations of a similar character. It is the property of the members absolutely and in exact proportion to their payments, and can be drawn by them or their nominees in accordance with the rules; and further, every member is made acquainted with the exact sum standing to his credit, and in a very simple manner. In addition to a general balance sheet, which is prepared annually, each member is supplied with a special statement of his account, showing at a glance the amount invested for him, the interest on that amount, and his contributions during the year with his share of the sick pay deducted, then the total sum standing to his credit and securely invested. An example of a private balance sheet may well be published, taking that of the first member on the Society's books.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

No. 1. Member's Name.—Mr. W. H. HEALE,
Messrs. Cheal, Lowfield Nurseries, Crawley, Sussex.

STATEMENT OF ACCOUNT FOR THE YEAR ENDING FEBRUARY 11TH, 1884.

Cr.	£ s. d.	Dr.	£ s. d.
Balance	28 5 0½	Deduct Sick Pay.....	2 2 6½
Interest	1 2 2	To Balance.....	41 3 8
Contribution	1 19 0		
	<u>£41 6 2½</u>		<u>£41 6 2½</u>
Balance.....	£41 3 8		

Treasurer.—JAMES HUDSON,
Residence.—Gunnersbury House Gardens,
Acton, W.

Secretary.—JOHN FRANCIS McELROY,
Residence.—The Gardens, Moray Lodge,
Campden Hill, Kensington.

By the above account it will be seen that the balance of Mr. Heale has increased to the amount of £3 1s. 2d. during the year, while his payments and share of the sick fund has only amounted to £2 1s. 6½d., the interest on his banked funds, plus 9s. 4½d., having secured him the above sum, and at the same time entitled him to the sick benefits of the Society if he had needed them.

This is a result, so far as we know quite unparalleled in the history of benefit societies, and therefore the Society under notice can scarcely fail to force its claims to the notice of all studious gardeners before they are too old to participate in its advantages, the limit of age

being forty-five years. Young men especially should seriously consider the propriety of joining such a Society as this in preference to a general benefit society, which cannot offer equal advantages.

After the re-election of Committeemen, and the addition of Mr. John Barry of the Royal Horticultural Society's Gardens, sundry votes of thanks brought the proceedings of the meeting to a close, the balance of the management fund being handed to Mr. McElroy as a small remuneration for his valuable services as Secretary during a period of sixteen years.

At the Annual General Meeting of the ROYAL HORTICULTURAL SOCIETY held last Tuesday in the conservatory, the Right Hon. Lord Aberdare in the chair, the following candidates were unanimously elected Fellows—viz., William Edmund Boyce, Samuel William Dancocks, Robert Ewing, Edwin Faux, Mrs. Field Fisher, H. T. Shorland Fooks, William Thomas Frost, John Kendall, James Livesey, Charles Edward Lyon, Rev. J. Norman, Francis J. Pearse, Sir John Rose, Bart.; E. Shuttleworth, R. A. H. Bickford Smith, G. Hendes Smith, Rev. Wm. Wilks.

— MR. STEPHEN CASTLE, writing from West Lynn, Norfolk, on the 9th inst., observes:—"To-night I have on the table a unique BOUQUET for the season, consisting of Snowdrops, Crocuses, Primroses, and Rosemary in full flower."

— WE regret to have to record the death of DR. JOHN HUTTON BALFOUR, M.D., F.R.S. London and Edinburgh, F.L.S., LL.D. of Edinburgh, Glasgow, and St. Andrew's, and lately Emeritus Professor of Medicine and Botany in the University of Edinburgh, who expired in Edinburgh on Monday last, at the age of seventy-five. He wrote much on botanical science, and stood high in public estimation. Professor Bayley Balfour, who was only on Saturday last elected to the chair of Botany at the Oxford University, is a son of Dr. Balfour, and assisted his father for eight years at Edinburgh.

— THE twenty-sixth annual FLORAL AND HORTICULTURAL FETE AT YORK will be held on June 18th, 19th, and 20th of the present year, when the usual liberal and numerous prizes will be offered for plants, flowers, fruit, and vegetables. The schedule enumerates ninety-seven classes, the prizes varying in value from £20 to 3s.

— MR. J. HAMMOND, Boldre Grange Gardens, Lymington, Hants, observes that "On page 90 a correspondent writes respecting SPOT IN MASDEVALLIAS. This is an old enemy to gardeners, but assumes different aspects in different plants. For instance, in the Rose and Chrysanthemum leaves, besides Orchids and Echeverias. I would advise Mr. Bardney to place upon both sides of the leaf warm sulphur with the thumb and finger or a small brush, at the same time ventilating the house more freely."

— MR. GILBERT has sent us examples of his CHOU DE BURGHLEY which are identical with those we have had from him in previous years. The heads were oval-shaped, much resembling in size and form a very large and well-grown Cos Lettuce, being tolerably firm but not hard, and very pale green in colour. When cooked the "Chou" was pronounced delicious by all who partook of it. It was as tender as Vegetable Marrow, and its flavour quite distinct from that of any Cabbage. One critical individual fancied it had a "smack" of Asparagus, another a "suspicion" of Scakale, but all enjoyed it greatly. A portion was boiled for half an hour and was tender and good, but another portion allowed to boil ten minutes longer was better—in fact, perfectly cooked, and we did not consider that either coals or time were wasted in the preparation of such an acceptable dish. A firm Cabbage cannot be properly cooked in less than half an hour. We have seen Chou de Burghley growing in many gardens, and in some the plants were compact and of a uniform size, while in others they were more or less irregular. We are not able to account for the difference, but it is quite sufficient to account for the various estimates that have been formed of this vegetable. We think Chou de Burghley will live as long as its raiser, and many will join us in the hope that that will be a very long time.

— "T. S." writes:—"Have any of your readers who have had

their HOLLIES INJURED BY SALT GALES observed that *Ilex Hodginsii* suffers much less than other varieties? This was my experience of that beautiful Holly when residing near the sea."

— MR. W. BARDNEY writes:—"RHODODENDRON EARLY GEM has been rightly named, for it is indeed a gem for flowering at this season of the year, and should have a place in every garden where flowers are required during the winter months. The flowers are in the style of *R. præcox*, but slightly larger, and the plant is dwarf and very much more compact than that variety. At one time I considered the last named the best early-flowering Rhododendron, but it is superseded by Early Gem. To show the earliness of this variety it may be mentioned that it will flower freely at this season of the year in a cold house without being subject to forcing. Beautiful compact plants can be grown in 6-inch pots."

— MR. JOSEPH MALLENDER, The Gardens, Hodsock Priory, Worksop, Notts, sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS IN JANUARY:—"Total duration of sunshine in the month, 22·7 hours, or 9 per cent. of possible. We had sixteen sunless days. Total rainfall, 2·77 inches; rain fell on seventeen days; maximum fell in twenty-four hours on the 23rd, 0·71. South-westerly winds prevailed most of the month, the average velocity 15·2 miles per hour. Mean temperature of month, 43·0°; maximum on the 22nd, 51·5°; minimum on the 26th, 32·0°; maximum in sun on the 27th, 84·3°; minimum on grass on the 29th, 25·6°. Warmest day on the 10th; mean temperature, 50·4°. Coldest day on the 2nd; mean temperature, 35·6°. Mean temperature of air at 9 A.M., 41·9°; mean temperature of soil 1 foot deep, 41·1°. Number of nights below 32° in shade, 0; on grass, 12. Highest reading of barometer on the 16th, 30·632; lowest on 26th, 6 P.M., 28·293. The month has been remarkable for the mild temperature, especially at nights, for the severe gales of the last week, and for the low barometer on the 26th. From December 9th to February 2nd inclusive, or for eight consecutive weeks, the shaded thermometer never fell below 32°. The first few days were wet, then came a fortnight of dry weather, and the last ten days were very wet. The gale on the 23rd was very severe, and many trees were blown down. From 10 to 11 P.M. the velocity of the wind was 61·5 miles per hour. Vegetation is very forward."

— THE interesting letter in a daily contemporary from Miss North, the celebrated lady artist whose wonderful gallery of pictures at Kew has attracted so much admiration, thus describes a portion of the SCENERY IN THE PRASLIN ISLAND, ONE OF THE SEYCHELLES:—"The next morning Dr. Hoad took me round to the valley of the Coco de Mer (*Lodoicea seychellarum*), on the other side of the island, in his boat. We passed close along the shore, amidst beautiful salmon-coloured boulders, many of the little islands with waving Casuarina trees on their tops, and fine large-leaved trees shading the sandy shore all along, varied with patches of Cocoa-nut and Bread-fruit, and above the deep purple-red stony-topped hills, with forests between, the famous Coco de Mer trees dotted here and there among them like golden stars. It was so rough as we got to the south-east angle of the Praslin that we had a few anxious moments in our little boat, and found that the breakers and low tide would not let us go the usual way, so we had to put out to sea, and go outside some other islands, among great rolling Atlantic kind of waves, and then sailed straight into the Coco de Mer valley—my great object. Fancy a valley as large as old Hastings quite full of the great yellow stars! It was almost too good to believe. They have a thick under growth, and we had started late, so I could only draw one tree in full fruit, while Dr. Hoad had a nut cut down for me. The outside husk is shaped like a Mango or a painted egg; it is the inner nut which is double. I ate some of the jelly from inside; there must have been enough of it to fill an ordinary soup-tureen—of the purest white, and not bad. The male tree grows a good third higher than the fruit-bearing tree; there are masses of imperfect fruits, like gigantic acorns, which never come to perfection. The trees grow fast to a certain point, but like the tortoises, very slowly after that."

— A CORRESPONDENT sends the following note:—"The annual meeting of the EALING, ACTON, AND HANWELL HORTICULTURAL SOCIETY took place in the Girls' School-room at Ealing on the 8th inst., and from the report of the Committee presented on that occasion it appears that there are nearly 400 subscribers to the Society, besides many local tradesmen who give special prizes in kind in the cottagers' classes; these include articles of dress for men and women, gardening

tools, pictures, clocks, cakes, and other articles of food, all of good value and very acceptable. The income of the Society in 1883 was over £460, a large sum of money for a suburban society to raise, and this was made up of annual subscriptions, special prizes, entrance fees, &c. £326 15s. 6d.; admissions to summer show, £113 17s. 4d.; to autumn show, £12 5s. 5d. It will, therefore, be seen that the Society is able to hold two exhibitions in a year, one during the second week in July, which is on an extensive scale. Something like 1250 entries were made on the occasion of the summer show in July last. The autumn show, which takes place in November, is made up of Chrysanthemums, fruits, and vegetables, and is very attractive. The Society is fortunate in being enabled each year to hold its summer show in the pleasant grounds of one of the residences in the immediate neighbourhood, and the show fixed for July the 9th next will take place in the grounds of Manor House, Ealing, the residence of the Misses Perceval, daughters of the Right Hon. Spencer Perceval. Much of the Society's success is due to the exertions of Mr. Richard Dean, the Hon. Secretary, who is entering on the ninth year of his service, assisted by a good working committee of amateurs and professional gardeners.

— MR. P. CONNELLAN, Colmore, Thomastown, sends the following particulars of fine Conifers at Woodstock, Innistioige, Ireland:—*Araucaria imbricata*—height, 52 feet; diameter of branches, 29 feet; girth of stem (3 feet up), 7 feet 1 inch. *Cryptomeria Lobbii*—height, 44 feet; diameter of branches, 18 feet; girth of stem, 4 feet 2 inches. *Cupressus macrocarpa*—height, 58 feet; diameter of branches, 48 feet; girth of stem, 8 feet 6 inches. *Picea cephalonica*—height, 58 feet; diameter of branches, 44 feet; girth of stem, 8 feet. *Pinus insignis*—height, 66 feet; diameter of branches, 43 feet; girth of stem, 8 feet 10 inches. *Pinus strobus* (Weymouth Pine)—height, 65 feet; stem, clear of branches, 57 feet; girth, 7 feet 7 inches. The largest common Silver Fir—height, 107 feet; diameter of branches, 59 feet; girth of stem at 4 feet from the ground, 14 feet 9 inches.—(*Irish Farmers' Gazette*.)

— THE MUSEUMS OF ECONOMIC BOTANY AT KEW have during the past year been thoroughly re-arranged, owing in part to the additional apartment provided at the building facing the Palm house, the construction of gallery in the Wood Museum, and the incorporation of the India collections from Kensington with those previously at Kew. Many objects of great interest have been added, and much further information with photographs of scenery have greatly increased the value of these wonderful collections. The first part of a new edition of the Official Guide has been just issued, and is devoted to the Dicotyledons and Gymnosperms, being sold at the moderate price of 3d. In this publication the following historical information is given respecting

— THE ORIGIN OF THE MUSEUMS:—The foundation and progress of these collections, not only by far the most extensive in existence, but the first of their kind established, may be briefly traced since the conception of their plan by the late Director of the Royal Gardens, Sir W. J. Hooker. In 1847 the building now occupied by Museum No. II., which up to that year had been in use as a fruit store-house, &c., was added, by command of Her Majesty, to the botanic garden proper. Permission was immediately sought by the Director to have one room of this building fitted up with suitable cases for the exhibition of vegetable products—objects which neither the living plants of the garden nor the preserved specimens of the herbarium could show. Sir W. J. Hooker's request was liberally met by the Chief Commissioner of Her Majesty's Woods and Forests, and the museum was forthwith commenced, its nucleus consisting of the Director's private collection, presented by himself. No sooner was the establishment and aim of the museum generally made known than contributions to it poured in from all quarters of the globe, until in a few years the ten rooms of the building, with its passages and corners, were absolutely crammed with specimens. Its appreciation by the public being thus demonstrated, application was made to Parliament for a grant to defray the expenses of an additional building for the proper accommodation of the objects, and the house occupied by Museum No. I., opened to the public in the spring of 1857, is the result. In 1881 the extension of Museum No. I on the west side, containing a new and commodious staircase, was erected at a cost of £2000, met by a grant from the India Office, in order to supply the additional accommodation required for the Indian collections mentioned below. From the Exhibitions of 1851 and 1862, and from the Paris Exhibitions of 1855 and 1867, large additions were made to the museums, both by the presentation of specimens and also by their purchase, aided by grants from the Treasury and Board of Trade. Many eminent firms

engaged in the importation and manufacture of vegetable substances have most liberally contributed various illustrative series. By the different Government departments, by our Colonial officers and foreign representatives, and by numerous private travellers also, the most important services have been and continue to be rendered. Besides these sources of contribution must be mentioned the reinforcement of the Indian element in the museum, first in 1878 by the collection of forest produce, presented by the Government of India (consisting of 1113 specimens), and secondly in 1880 by the transference to Kew of the entire economico-botanical collections, forming part of the India Museum at South Kensington. From these about 4000 specimens were selected for permanent exhibition; these are distinguished by a light blue label bearing the words "India Museum."

— A FRUIT-PRESERVER writing to the *Liverpool Courier* upon FRUIT FARMING observes that "Mr. Gladstone has recently stated that the number of acres of fruit grown in this country has only increased by 27,000 acres in the last nineteen years, and that 24,000 out of the 27,000 acres has been in five counties only. I have no doubt that this is quite true, and the counties referred to are those immediately around London. Other counties at a further distance from London go in for only partial cultivation of fruit, say Cornwall, Devon, Gloucester, Worcester, Hereford, Shropshire, Cheshire, and Norfolk: but a large proportion of other English counties do not grow fruit to any extent as compared to the acreage under cultivation of other products, and I am compelled to draw very large supplies from the counties immediately round London, of which Covent Garden and other London markets are the centre. I have for many years been of opinion that if the British farmers would put an increased portion of their soil under the cultivation of Gooseberries, Raspberries, Strawberries, Black Currants, Plums, and Damsons, it would pay much better than their present mode of working. The manufacture of fruit preserves is beginning to take a new position in this country, and is now being largely used. It is, however, incorrect that jam is charged from 7d. to 9d. a lb., and also that it is owing mainly to the energy of the French, Belgian, Dutch, German, and American fruit-growers. No doubt the first four countries do give a supply of some kinds of fruit for the manufacture of jam, principally Plums, but I am not aware that America sends us any fruit whatever for jam-making. By far the largest proportion of fruit used for the manufacture of jam is grown in this country. My usual season's make is Gooseberry, 300 tons; Raspberry, 300 tons; Strawberry, 200 tons; Black Currant, 400 tons; Damson, 500 tons; Blackberry, 100 tons; and they can be bought retail from any ready-money grocer at the following prices:—Gooseberry, 5d. to 5½d. per lb.; Raspberry, 6d. to 6½d.; Strawberry, 6d. to 6½d.; Black Currant, 5½d.; Blackberry, 5½d.; Plum, 4d. Mr. Gladstone is therefore in error in stating that the jam consumed in this country is not English-made jam. I have never seen a single package of French, Belgian, Dutch, German, or American jam offered in this country."

ROYAL HORTICULTURAL SOCIETY.

THE Annual General Meeting of this Society was held in the conservatory at South Kensington on Tuesday the 12th inst., the President, Lord Aberdare, in the chair, and the following members of the Council were present:—Sir Trevor Lawrence, Bart., M.P., Dr. R. Hogg, G. F. Wilson, Esq., E. G. Loder, Esq., W. Lee, Esq., W. Haughton, Esq. (Treasurer), and Major F. Mason (Secretary). There was a fair attendance of Fellows.

The proceedings were commenced by the Secretary reading the announcement calling the meeting, the minutes of the last general meeting, and the names of gentlemen proposed and duly elected as Fellows of the Society. Dr. Masters and Mr. Noble were then appointed scrutineers of the ballot for the election of officers and members of the Council for the year—namely, members of the Council:—The Right Hon. Viscount Enfield, Professor Michael Foster, F.R.S., and Frederick Du Cane Godman, F.R.S. Officers:—President, Lord Aberdare; Treasurer, William Haughton; Secretary, Major F. Mason; and Auditors, John Lee, James F. West, and W. Richards. It was subsequently announced that these had been all duly elected. An alteration in one of the bye-laws to facilitate the work of the Treasurer in regard to signing the receipts for Fellows' subscriptions distributed to the Fellows was proposed and adopted, and the annual report which follows was then taken as read.

ANNUAL REPORT FOR 1883

The Council congratulate the Fellows on the financial position of the Society, the revenue of the year having been sufficient to satisfy the debtor balance carried forward from the preceding one, and to give a considerable surplus after paying or providing for the payment of every liability to the 31st December last.

The Council regret that some of their Fellows should have felt aggrieved by the partial curtailment of their enjoyment of the gardens, which was necessitated by the holding of the Fisheries Exhibition; but apart from the fact that this curtailment was unavoidable, the Council have the gratification of believing that the great majority of Fellows found ample compensation

for any loss they suffered in this respect in the large privileges which they enjoyed in connection with that Exhibition.

The Council have the pleasure of being able to announce that they have succeeded in arranging with the Executive Council of the International Health Exhibition that Fellows shall have in respect of this Exhibition the same privileges, except as to the opening ceremony and six evenings which may be reserved, as they enjoyed during the Fisheries Exhibition.

The Council take this opportunity of recognising the spirit of friendly consideration for the interests of the Society which has been shown by the executive of each of these exhibitions, and the liberality of the Council of the International Health Exhibition, which enables them to present to each former debenture holder of the Society a ticket, giving all a Fellow's privileges of admission, but not transferable, in addition to the privileges granted to him last year.

In the early summer an experiment was made in the form of two evening meetings, which the Linnean Society very kindly allowed to be held in their rooms at Burlington House.

On both occasions a large number of valuable plants were arranged in the library, including Orchids sent by Sir Trevor Lawrence, Mr. Lee, Messrs. Veitch, and others; Rhododendrons by Mr. Mangles; herbaceous and other plants by Miss Jekyll, Mr. Loder, Mr. G. Maw, Mr. T. Ware, Messrs. Barr, and others, as well as specimens from the Royal Gardens, Kew, and the Society's gardens at Chiswick. The company assembled in the library some time before the reading of papers commenced showed very great interest in the examination of this collection of flowers. On both occasions the chair was taken by the President, Lord Aberdare, strongly supported by members of Council.

At the first meeting on May 8th, after some appropriate introductory remarks by the Chairman, Dr. M. Foster, F.R.S., gave an account of the onocycus groups of Irises, dwelling on the characters of their construction, their botanical affinities, their geographical distribution, and the proper method of culture. His remarks were illustrated by means of large diagrams, and with freshly cut blooms of *Iris iberica*, one of the best known of the group. A discussion followed, in which Sir J. Hooker, Mr. H. J. Elwes, and Mr. J. G. Baker took part. Mr. E. G. Loder then read a paper on hardy Cacti, giving an account of their affinities and distribution, and describing the method of culture, which in his hands has proved so successful. Dr. Hogg followed with an account of some Australian Apples, recently imported, exhibiting specimens and distributing them freely among the audience. The meeting was brought to a close by Dr. Foster briefly describing and exhibiting on behalf of Herr Max Leichtlin several new plants recently flowered at Baden Baden.

At the following meeting, June 12th, the reading of papers began by "Notes on Conifers," by Dr. Masters, F.R.S., in which the author drew attention to the mode of growth and to other physiological features of certain Pines and Firs. Mr. W. Goldring followed with a paper on "Cypripediums," admirably illustrated by a very large number of choice Cypripediums in blooms, kindly sent by various gentlemen. The author passed in review some of the leading types of the genus, as well as the striking hybrids recently produced, and an animated discussion followed. Mr. G. Maw then gave an account of the genus *Crocus* (concerning which he, as is well known, is the highest authority), dwelling particularly on the light which a knowledge of the geographical distribution and habits of the various species and varieties may be made to throw upon the culture most likely to be successful.

The experiment of these meetings may certainly be considered most encouraging. The audience was not only large, well filling the Linnean Society's meeting-room, but included besides the gentlemen incidentally mentioned above, many distinguished horticulturists, and several Fellows of the Linnean Society. Great interest was shown both in the papers read and in the discussions which followed, while the opportunity afforded for examining and conversing about so many beautiful or rare plants helped to make the evenings very enjoyable, and repeated expressions were heard of the desire that more of such meetings might be held.

The gardens at Chiswick have been maintained in a high state of efficiency, the practical work of the Society being carried on as usual. Fellows and their friends visited these gardens in larger numbers than during past years.

The trials by the Fruit and Floral Committees comprised respectively Peas (of which 154 samples were tried), Potatoes in great variety, Lettuces, Tomatoes grown in pots and in the open ground, and Celeries among vegetables; and among flowers and plants, Pelargoniums, Verbenas, Sweet Peas, Begonias, single Dahlias, Tydeas, Gloxinias, and others.

It is proposed that trials shall be made during the present year by the Fruit Committee of new varieties of Potatoes and Peas, and of the entire class of Cauliflower and Broccoli, which is in great confusion; and by the Floral Committee of new Pelargoniums, Begonias of the Rex or handsome-foliaged type, Ferns of the Adiantum or Maidenhair class, and Chrysanthemums. Fellows of the Society and other cultivators of any of these plants, &c., are invited to contribute for this purpose.

Facilities were afforded to the Committees of the Pelargonium Society and the International Potato Society for the trials of new varieties of the objects submitted to these bodies respectively for cultivation.

The success attending the novel experiment of the Apple Congress at Chiswick surpassed the most sanguine anticipations of the Council, such a display of different varieties, of which the Society's garden contributed 260, having never before been seen. About 10,000 persons visited the Exhibition, which enabled the Fruit Committee to obtain much valuable information in connection with the fruit exhibited. A report embodying this information is being prepared for publication.

It is contemplated, should the season prove favourable, to hold similar shows of other fruits.

The number of plants required for distribution to Fellows continues to increase. During the past year 19,470 plants in pots have been sent out with 30,000 packets of seeds, and about 5000 cuttings of Vines and other fruit trees, the number of Fellows availing themselves of this privilege being 997.

The cost of repairs during the past season shows some increase, the great vinery having had to be repainted and several plant pits renewed.

There were among the Fellows during the year 135 new elections, 147 resignations, and fifty-seven deaths, twenty-three of these deaths having been those of life Fellows.

In commenting on the above report and the condition of the Society, the President, Lord Aberdare, remarked that their position that day indicated that the Society is in a state of transition, but there were several facts which gave cheerful hopes for the future, as, though there had been a falling-off in the number of elections during the year, there had also been a reduction of expenses. No doubt that some members had been lost owing to the partial severance of the Society from the Kensington Gardens, which had been very attractive to residents in the neighbourhood. But this loss had not been so great as he expected, and he believed that no Fellows had resigned who had joined them simply from a love of horticulture and a desire to further its interests. Therefore, the scientific and practical importance had not been decreased in the slightest degree. The previous year the elections were 147 and the resignations 124; in the past year the elections were 135 and the resignations 147. Returning to the financial aspect his lordship stated that during the five preceding years there had been an adverse balance on each occasion, but this year, after clearing off all debts and doubtful assets, there is a balance of £800 to the good. This was chiefly due to the liberal arrangements the Committee of the Fisheries Exhibition had made with the Society, and partly to the reduction of expenses; but though this thus derived from what might be termed accidental causes it had placed them in an extremely good position with regard to the present year, in which he considered they would be able to increase the strength of their finances.

Arrangements have been made with the Executive Council of the Health Exhibition securing to the Fellows similar privileges to those enjoyed by them in connection with the Fisheries' Exhibition—i.e., free admission while the Exhibition is continued, except to the opening and closing ceremonies, and upon six evenings to be reserved by the Council, the debenture holders also being entitled to obtain passes. It is also proposed to continue the monthly evening meetings, which proved so successful last year, and which the Chairman thought would add much to the scientific importance of the Society. No large shows are to be held, but it is in contemplation, though the arrangements have not yet been completed, to hold monthly exhibitions of flowers and fruit in a building to be erected for the purpose at the expense of the Health Committee, but under the care of the Royal Horticultural Society. If this can be settled upon, it will be greatly to the advantage of the Fellows, and no doubt some extensive displays would be obtained, as one of the usual fortnightly meetings would be held upon the same day. He concluded by submitting that the report be adopted.

Mr. Shirley Hibberd, in seconding the adoption of the report, stated that it was gratifying to hear of the Society's satisfactory financial position; but it should be remembered that this was due to money acquired by accident and did not indicate increased moral strength. Any comfort derivable from the report seemed to be chiefly speculation as to the future, and he regretted that the announcements respecting the programme of the present year had been made so late that the Special Societies which had added so much to the attractions of the Society had been compelled to fix the dates of their shows in much uncertainty as to where they would be held. He considered the fortnightly meetings are in danger of becoming merely trade exhibitions, and he thought it was desirable that the Society should expend more money in connection with the meetings with a view to encouraging amateurs. It was said that gentlemen sending their plants and fruits to the Society's meetings must not expect money prizes, but the gardeners looked for some compensation, and he was convinced that a moderate sum judiciously expended would do much to increase the number of amateur exhibitors, and thus render them better representatives of general horticulture. Referring to Chiswick Mr. Hibberd thanked the Society on behalf of the Committee of the International Potato Show for the liberality by which a space of ground had been placed at their disposal for testing varieties of Potatoes both in the last and present years. He also wished that Fellows would visit the Chiswick Gardens more frequently than is the case, as there is always much to interest them, though there is room for several improvements in regard to the labelling and other matters.

In reply Lord Aberdare called Mr. Hibberd's attention to the fact that though the increased receipts was accidental, the decrease in expenditure was permanent. It was further stated that only medals had been given at the meetings, and it was the general opinion that the displays had greatly improved. It does not therefore appear that money prizes are needed. The Chiswick Gardens had been under consideration, and it was proposed to expend a portion of their surplus upon improvements there, as the Society depends greatly upon this garden.

Some discussion arose respecting the approaches to the conservatory, but it was explained that when the Health Exhibition is opened Fellows can obtain admission at any door; until then the north-east door is reserved for them, and they will have access to the conservatory only. The report was then adopted, and the meeting terminated with a unanimous vote of thanks to the Chairman.

[In consequence of an accident occurring in preparing for press we are unable to publish the auditors' report and balance sheet.]

LATE-FLOWERING CHRYSANTHEMUMS.

ALMOST any flowers are useful in the dull months of winter. I have found amongst Chrysanthemums Julie Lagravère a very serviceable variety, having had fresh flowers of this until the 24th of January from plants which we have been cutting for six weeks. Countess of Dudley has proved useful, having flowers which look likely to keep till the middle of February. This is a variety that has not come under my notice before. I should feel obliged if any of your readers would say what they know of it; I cannot find it in any of the lists of Chrysanthemums that have reached me. The plants I refer to were stopped about the middle of August. Other varieties were pinched at the same time with poor results—White Christine, Beverley, Diamond, and a few Japanese, which produced small mis-shaped flowers, while many of the buds did not open at all. With Julie Lagravère Snowdrop would be a

good companion, its pearly white flowers being naturally late, and it is a good keeping Pompon.—J. P.

WITH us the Chrysanthemum season is not over yet, as you will see by the blooms which I send you. Fair Maid of Guernsey is from a plant that was cut back to about a foot from the pot in July, showing that by that system useful blooms may be had during January and February. And how serviceable they are during these months! Guernsey Nugget is just now at its best with me, and Princess Teck fresh and fine, the blooms on disbudded and undisbudded plants being very good. Père Delaux appears to be a good late Japanese variety. I attribute their lateness partly to the very mild autumn and winter.—WM. JENKINS.

[The flowers sent are very fresh and attractive, and there is not a speck of mildew on the foliage. The plants have evidently received good attention. Another correspondent states that by cutting down some plants he has a valuable supply of late flowers. For producing dwarf plants for exhibition only the earliest varieties may be cut down in June. Cutting down all sorts indiscriminately in July is a mistake when blooms are wanted in November. Such a mistake is, however, not likely to be made by many thoughtful cultivators.]

SPECIAL SOCIETIES.

I HAVE no wish to enter into controversy with Mr. Douglas, and, like your correspondent "Border Flower," object to giving the name of the amateur to whom I alluded; but, like him, I have sent it to the Editor, that he may use his discretion as to giving it to Mr. Douglas or not. As to your correspondent "W. J. H.'s" question about pedigree Roses, I object to the term because it is misleading. Pedigree has reference, so Richardson says, to "the genealogy of forefathers;" and when we speak of pedigree Shorthorns (*e.g.*) it is that we can trace for some generations the stock from whence they came. But because you cross two Roses you are entitled to call the progeny a pedigree Rose seems to me ridiculous. Why not speak of pedigree Geraniums or Auriculas, or any other flower of which you know the parents?—D., Deal.

I AM very loth to further trouble you regarding this matter, but Mr. Douglas in your last issue rather assumes that "D., Deal," was referring to an amateur who had an overstock of good Auriculas to dispose of. What "D., Deal," really said was:—"In the class for pairs there were fourteen instead of nine exhibitors, showing unmistakably the wisdom of making this class so as to admit small growers, although I cannot but think an unfair use was made by some exhibitors of this class." Further on your worthy correspondent "D., Deal," refers to the individual complained of as "he."

Let us see who competed in the class in question and obtained prizes. Your issue of 26th April, 1883, page 340, shows that the following took the prizes in the order named—Messrs. S. Barlow, P. K. Penson, W. Brockbank, C. Turner, M. Rowan, and W. Bolton. I observe later on that Mr. C. Turner took every prize in the two classes for a single specimen gold-centre Alpine Auricula and a single specimen white or cream centre Alpine Auricula. Comment is needless, the more so as Mr. Douglas seems to think this is as it should be; but he does admit that a man who had a surplus stock of a thousand plants ought not to have competed in the class for two Auriculas, adding in a guarded manner, "I do not think it was done."

A perusal of the list of winners in the particular class under notice will convince Mr. Douglas that such was really the case, or I am sure "D., Deal," would not have called attention to the matter in the terms he did.—AURICULA, North London.

I THINK your correspondent "Border Flower" has hit the right nail on the head. I am told, it may be wrongly, that Mr. Douglas sells more Auriculas than any nurseryman in the kingdom (Mr. Turner excepted); while Mr. Cannell advertised last year that he had bought all his surplus stock of Carnations and Picotees; while Mr. Dodwell must be considered quite a nurseryman. He publishes a catalogue of his own seedlings, priced at 10s. and 5s. a pair, and Mr. Cannell advertises this year that he has bought his surplus stock. It would be surprising, therefore, if the two Secretaries did not see cogent reasons why the two Societies should flourish!—FAIR PLAY.

VINES BLEEDING.

I HAVE much pleasure in informing "Comber" (page 60) that the Vine which bled so profusely here after having one of its limbs cut off last April is alive and well. He will remember I did not say bleeding was injurious, beneficial, or harmless; but I pointed out that some were of one opinion and some another on this subject, and the case in question ought to point to a conclusion of some kind. Whether it has done so or not your readers may judge.

From the time the Vine was pruned until the shoots had gained a length of a few inches between two and three gallons of sap were lost. It was a Foster's Seedling with three main rods, and one of them was cut away to make room for an Alicante. In the same house were some rods of Black Hamburgs. These grew fast enough, and the Foster's Seedling kept pace with them in every respect. There was no shyness in forming shoots, with two and three bunches on each, as is usual with this variety. Wood and leaves developed as strongly as ever they did previously, and the bunches matured in the ordinary

way. Indeed the whole appearance of the Vine from then until now indicates unimpaired energies, and last midsummer no one could have told it had ever lost a drop of "blood." I had a drink of this latter, and it gave me the impression of being water, pure and refreshing. Some of it which was put into quart bottles, corked up, and kept for a time, never changed in character.

"Non-Believer" (page 80) speaks very boldly all at once; but why did not he take the matter up when I asked your readers to predict what would be the result of our Vine losing so much sap? We should have known by this time how much his teachings were worth on the subject. He sees from "Comber's" note that I do not believe Vines are injured by bleeding, and armed with this knowledge of my opinions, he puts forth what he terms a challenge on the matter; but this only corresponds with the hackneyed phrase indulged in further on—"If they decline the challenge, I and others of your readers will no doubt form our own opinions," and "I never saw . . . and never knew anybody either who did," are expressions used by some writers in every gardening paper where they could get them in for the last twenty years, but now they only provoke a smile. Are they inserted for the amusement of readers?—J. MUIR, *Margam Park*.

THE Vines here were planted in the spring of 1881 in borders inside—viz., old Pine pits, as stated exactly by Mr. Challis on page 36, only these pits are divided by a 4½-inch brick wall, so that at any time one part could be renewed without disturbing the other. The Vines in one part of the pit received 680 gallons of water previous to starting them this year, the other half had 170 gallons, both in the same house. The first commenced bleeding (and are bleeding still) the same day as watered; the others show no signs of bleeding. This I have tested two years, and must, I should say, prove that the watering helps the bleeding; but if this lost sap, or water, has no nourishment for the coming foliage, and that is only supported by stored-up sap till the Vines commence making fresh roots, we may rest content that it is doing no harm, but I have always seen it in another light. The Vines in question have exceeded our expectation, and have been cropped from the first. I have seen no great difference in the crop as yet, bleeding or no bleeding; but this year I may be able to form a better opinion, as I am watching this closely and other treatment from the time of planting.—BLACK PRINCE.

ELECTION OF CARNATIONS AND PICOTEEES.

THE ELECTORS' RETURNS.

[The names of the raisers of the varieties in the following lists have been given in the previous returns.]

From Mr. THOS. MADDOCK, gardeuer to J. Ramskill, Esq., Lofthouse Hall, Wakefield.

CARNATIONS.

FERNS AND THEIR CULTIVATION.

(Continued from page 103.)

I BELIEVE good leaf soil will suit any Fern as well as peat, and in the case of Adiantums will not be so injurious. Take for instance that queen of the genus *A. farleyense*. I remember when *A. farleyense* was new, and small plants were selling at from 20s. to 30s. each, we had several in splendid condition growing in strong loam, leaf soil, and sand. A gentleman who had seen our plants went to a nursery a few miles from Manchester and saw some very miserable-looking plants in declining health, and remarked to the proprietor about their want of vigour. "Oh," said he, "*farleyense* is no use,

it cannot be grown; we are giving it up as impossible." One of our specimen plants we exhibited at Old Trafford about that time or soon after, and it was admired by all who saw it. Some years after this, when our supply of leaf soil was exhausted, we resorted to the use of peat, and almost lost our stock of *A. farleyense*, although we had some hundreds. I felt sure the peat did not agree with them; had them turned out of the pots, their roots washed, and potted again into good loam, and, I think, cinders or sand, and in a few days the change was marvellous. They commenced growing, and soon became strong healthy plants. That lesson has made me fight very shy of peat for *Adiantums* ever since, and we use very little indeed in our compost for Ferns. I am satisfied that good rich loam with a sufficient

and their rhizomes or creeping stems in the damp moss, they grow luxuriantly and make objects of great beauty. This also appears to be the best method of growing the *Platynerium*, since it allows the water to drain freely away, while the moss holds enough moisture to support them for days. Another important advantage of growing *Davallias* and *Platyneriums* in this way is that it gives the room which they would otherwise occupy on stages and shelves for the convenience of other plants.

[An engraving (fig. 26) is given of *Davallia hemiptera*, a very distinct species of good habit.]

In all these cases I have laid emphasis upon the importance of good drainage, for though Ferns love plenty of water at the roots they do not like it to remain there stagnant, excepting in such kinds as the *Osmundas* already mentioned. But let me here say a word about the injury often done to Ferns by watering or syringing them. When grown under glass the greatest care ought to be taken not to wet the foliage, and especially in dark weather; for the result of water lodging on the fronds is often seen in ugly dark stains which never come out, but remain an eyesore till the fronds so stained are removed from the plants. Moisture generated by sprinkling the paths and walls is the most congenial to the plants, and may be produced without the risk of disfiguring the foliage. Then, again, the water applied to the roots should be of the same temperature as the atmosphere of the house in which they grow, so that no check is given to the plants. I am impressed with the idea that when rain falls on rocks which have been long exposed to hot sun it must attain a high degree of heat before reaching the roots of the plants below, so that we need not fear that warm water will do harm to tropical plants growing in a high temperature; but we have every reason to fear injury from the application of water which is too cold.

As to the potting of Ferns, I need only remark upon the necessity for open compost, and that not too firmly pressed in the pots, and especially do not overpot. Small shifts as frequently as the soil become filled with roots will be followed by the best results, while overpotting is often the cause of failure, sickness, and death overtaking the plants so treated.

With respect to insects, some Ferns appear to escape their depredations altogether, while others are with the greatest difficulty kept clear of them. Of mealy bug I have had such little experience that I do not feel qualified to speak about its attacks upon Ferns. We have had trouble enough sometimes with bug on Ferns we have received from other places before we have felt at liberty to put them along with the general collection, taking care to catch and kill all the insects we could, as the plants have been examined from day to day for a long time, though unless the plants infested are scarce and valuable they are not unfrequently thrown into the furnace and burned, plant, soil, and crocks altogether.

Thrips are great pests on many Ferns. Fumigating with tobacco or tobacco paper seems to be the best remedy (but this needs to be done very carefully or the Ferns will suffer greatly), and it will probably require repeating several times before all the thrips are destroyed. Very frequently Ferns are attacked by thrips because they have too much artificial heat. Many from Japan, New Zealand, Australia, and North America being hardy or nearly hardy, are sure to be preyed upon by insects if kept too warm. In the lovely family of *Gleichenias* are many which require very little artificial heat except to exclude frost, some of them not being injured by a few degrees of frost, but very liable to the attacks of thrips in heat. Scale may be destroyed by Mr. Hugh's capital insecticide, fir-tree oil, carefully used. Green and white fly will meet their death in the fumigations for thrips. Where only a few plants are infested with thrips or fly they may be dipped, if small enough, into the fir-tree oil solution, or in water containing soft soap in the proportion of 2 ozs. to a gallon of water, or treated to the spray of fir-tree oil from the spray-distributor. Speaking of soft soap and water, I find

Fig. 25.—*ADIANTUM RUBELLUM*.

admixture of cinders or broken stone and leaf soil is the safest for general use.

[*Adiantum rubellum*, shown in fig. 25 is a charming Fern when well grown, its young fronds having a distinct rosy tinge. *A. ciliatum* fig. 27, page 133, is very useful for a basket or pot suspended from the roof of a fernery, its long narrow fronds being gracefully pendent.]

In the case of such Ferns as *Pellæas*, *Nothochlænas*, and *Aspleniums germanicum* and *septentrionale* and *Ruta-muraria*, and small Ferns whose natural habitats are crevices in rocks and walls, I find it an excellent plan to place the roots between two flat pieces of broken stone in potting, and also to use small pieces of the same mixed with the soil to secure abundant drainage and free passage for the air to the roots.

Respecting *Davallias*, I find many of them grow exceedingly well suspended from the roof of the house or against the wall, with their roots in moss containing compost, fastened on pieces of cork with thin copper wire. Here, with their fronds well exposed to the light

it convenient sometimes to beat it into a lather, and apply the lather to the plants, as being more effectual than dipping; and I may here say this is an excellent way to dispose of green fly on Roses out of doors, for this lather is certain death to them if used on the shoots where they are clustered together. I find one or two applications in the season quite enough to keep Roses moderately free from aphides.

I ought to mention the necessity for securing constant moisture about the roots of Ferns planted out of doors. A good supply of leaf soil or peat should form a part of the composition in which outdoor Ferns are to grow, so as to secure them against drought in summer time; and the addition of stones on the surface of the ground is most valuable, as they become great protectors from wind and sun, and are splendid conservers of moisture in the earth. I once read in one of the gardening periodicals a remark to this effect, that many gardeners sin against themselves in raking all the stones out of the ground they cultivate. I am fully persuaded of the truth of that remark, for I have been astonished to see the health and strength of vegetation on land which seemed to be half stones, and on hillsides where broken rock was more plentiful than earth. I am satisfied that such rocks and stones secure two essential objects—viz., protection from the drying influence of sun and wind, and sufficient looseness of material to allow the air to get well about the roots of trees, shrubs, and Ferns, or whatever grows in such material.

PEACH TREES CASTING THEIR BUDS.

I BELIEVE that more uncertainty exists on this question than upon any other connected with Peach-growing. I do not think that spring water will cause the buds of Peach trees to fall unless it contains some ingredient hurtful to vegetation generally. I am troubled each year by Peach buds falling, and think I know the cause, and in time hope to remove it. It may do good, therefore, to indicate the conditions under which it exists here.

Our Peach trees occupy the north side of a half-span house which till last autumn was planted with Vines on the south side. The Vines have now been removed, and the south side is occupied with a curved trellis planted with one-year-trained Peach trees. The trees on the north side have been planted perhaps fourteen years. I have had charge of them six years, and every year they have cast a considerable part of their buds; sufficient, however, always remaining on the trees to afford a crop of fruit, which ripens to perfection. When the Vines were in the house the Grape could not be cut till after Christmas, and consequently in our moist climate fire heat with a little air was necessary for the preservation of the Grapes, and to this firing after the Peach trees had cast their leaves I attributed the dropping of the buds, till this year, when I find I have been wrong, as part of the buds have dropped and a few are still dropping, while next to no fire heat has been used. Only on one or two occasions have we had to make the pipes more than lukewarm to keep out frost and damp from bedding plants and other softwooded plants kept in the house.

I have asked many experienced men at one time and another how they account for the dropping of the buds, and in most cases the answer has been that the border has been too dry in winter; but that is not the case here, as the border has always been moist at a depth of 18 inches when it has been examined, and I make a point of keeping Vines and Peaches well supplied with water at all seasons. Gishurst compound is used as a winter dressing, but not of sufficient strength to do harm, and I do not think that even a much stronger solution would prove injurious to healthy trees. A neighbour of mine who grows Peaches well says that he has frequently used it at the rate of 8 ozs. to the gallon of water.

My trees are growing in a very unsuitable soil for fruit trees. Judging from the condition in which it is now I should say that originally it was taken off the common, where there is abundance of tempting turf full of fibre, but that is all, and when that decays it becomes totally unfit for fruit trees. It does very well for bedding plants or anything else that has not to remain long in it. I have seen fair crops of Cucumbers grown in it with the aid of liquid and other manures. It is to this soil that I now attribute the casting of the buds, and as soon as the young trees, planted last autumn, commence bearing fruit, I shall

Fig. 26.—DAVALLIA HEMIPTERA.

endeavour to remove the evil. It is possible that the shade caused by the Vines may have prevented the thorough maturation of the young wood, as no blooms have fallen off the natural spurs formed on the old wood; but I think that would not account for all the evil, because not a hundred yards from where I write there is a span-roofed house with Vines on the roof and Peach trees in the centre under the Vines, and no buds fall there, but neither Vines nor Peaches make very vigorous growth. I shall be glad if this raises a discussion upon this important matter, as it deserves some consideration in the Journal, and if any light is thrown upon it, I, at least, shall have one more cause for gratitude to the paper I have admired for many years.—T. A. B.

IN reply to "L. T." the Peach trees outside are not affected the same as those inside, and I may also mention that they were watered from a different source—viz., a sewage tank close at hand.—ALPHA.

DRACÆNA GOLDIEANA.

THIS plant is by no means difficult to propagate, yet it is slow, and a long time must elapse before a stock can be raised if only one ordinary trade size plant is obtained to start with. The time necessary to raise a stock is undoubtedly the cause of its price at the present time, which has been maintained at a higher rate than any fine foliage plant of recent introduction. It has been said that gardeners do not appreciate it, and I certainly did not after obtaining a small but expensive starved plant which took me two or three years to grow into a specimen, but at the present time I think differently. I feel persuaded that this *Dracæna* will become one of our most popular plants, both for the embellishment of stoves and the furnishing of dwelling-rooms. The marbled markings of the foliage have a very pleasing effect, and show even more clearly by artificial than by natural light. Its foliage is strong and leathery—in fact, like *D. gracilis* in this respect, which is one of the best *Dracænas* that can be grown for room-decoration. Another advantage it possesses, and one that is of importance when plants are required for vases of a certain size, and that is, it can be grown when fully 2 feet high with large well-developed leaves in 5 and 6-inch pots. This is not the case with *Dracænas* generally, for to develop them as they should be they enjoy liberal root room. *D. Goldieana* and *D. gracilis* are exceptions to this rule, the former being very much finer rooted than any other variety.

Another recommendation this plant possesses is that large well-developed heads can be taken off and rooted without losing a leaf or making small ones at the top after it has become rooted; such at least, so far, has been the case with me. The orthodox system of mossing must not be practised, for I should be afraid to speculate on the length of time it would take before the stem emitted roots. The system to adopt is to take off the head at a joint where the wood is not too firm, for the firmer the base of the stem of the head the longer the space of time it will take to root. If the plant is strong and vigorous it should be severed about 1 foot from the top. The base must be cut clean with a sharp knife, and none of the foliage removed. The head should be inserted in a 4 or 5-inch pot filled with equal parts of loam and peat in which has been mixed a liberal dash of sand. A little of the latter should be placed in the centre for the base of the stem to rest upon. After insertion a good watering should be given, and the position in which they are to be placed entirely depends upon the season. At the present time, or when the sun has not much power, any position will do providing bottom heat can be given and a night temperature of 65° maintained. No propagating frame or handlight is necessary, for I am convinced the cuttings root better when treated like Pine suckers. In summer we should, however, place them in a frame or handlight if we could not guarantee keeping them well shaded from the sun without. The leaves, even if placed in a close propagating frame, never show signs of damping, as *Dracænas* generally do if highly coloured.

A portion of the remaining stem of the old plant nearest where the head was taken may be cut into lengths with a leaf attached and inserted in small pots, and every one in due time will root and form a plant. When the stem is thoroughly firm we do not advise it to be cut into lengths because they take so long to root, but place the plant in strong brisk heat, and when young shoots are made near the top slip them off with a small heel and root them. This is slow but sure, and many plants can thus be produced from one. Those raised from the stem will never make such fine plants in appearance as the heads make, but they can be grown on until they are strong, and then their heads can be rooted. By this means a stock of very fine plants can be produced. Plants in 5 and 6-inch pots from 12 to 18 inches high with large fine foliage to the base are conspicuous specimens for standing singly in vases. When well grown it is also a very striking plant in the stove, and fortunately does not quickly grow too large for purposes of decoration. —W. BARDNEY.

CARNATION SOUVENIR DE LA MALMAISON.—The rose and flesh-coloured varieties of the above *Carnation* are great favourites with most people. The blooms individually are of great size, and the fragrance delightful. They are very useful for conservatory decoration, also for cut flowers, as a single bloom will scent a large room. If large plants are required the old flower stems should be removed, the plants turned out of the pots, some of the old soil being removed, and then the plants placed in larger well-drained pots. The shoots should be layered equally over the pot. Healthy foliage down to the rim of the pot is thus obtained, and each layer has its own roots to support it, consequently much finer blooms are secured than by only having the old stem to

support all the shoots. If there are more large plants than are required, and it is wished to increase the stock, each layer may be taken off when rooted and potted singly. These are very useful to associate with small plants in the conservatory.—A. YOUNG.

FRUIT-TREE CANKER AND ITS CAUSES.

THE Astwood Amateur Gardeners' Society have had this subject before their meetings four or five weeks, with the results chronicled in the enclosed extracts, some parts of which perhaps might be worth a discussion in the *Journal of Horticulture*, which could not fail to be interesting and might be profitable.—J. HIAM.

[We readily publish the following summary of the proceedings of one of the meetings referred to.]

"The discussion on canker and its causes was resumed by Mr. Hiam, who said:—Gentlemen, you are all, no doubt, aware of the nature of the subject we intend to discuss and examine to-night; it is the postponed examination of insects, &c., by the aid of the microscope, in order, if possible, to arrive at the cause of so many fruit trees, such as Apples, Pears, Apricots, and Plums, cankering and dying prematurely. I will not occupy your time with a long paper on my own opinions, because I feel sure we shall be far better and more interestedly employed in observing the various insect life taken from the trees in a cankered state. I intend to submit three questions to the meeting for discussion, in order, if possible, to obtain the opinions of others, and I trust the replies will be short and to the point in order to save time. 1st, What is canker, as generally understood in fruit culture? My own reply is, that it is a premature decay of the wood, often the young vigorous shoots of one year's growth. 2nd, What is the cause? It is generally attributed to bad drainage of the subsoil; but not unfrequently we hear that the roots "are on the gravel," that was the only reason given that I can remember in my young days. Another will tell us that it is owing to sudden changes of temperature or climatic causes, such as from severe frosty nights followed by hot sunny days in spring. Then, again, we have some sorts of Apples which are, undoubtedly, more subject to canker than others. My idea is, as you are already aware, that we may, by careful investigation, with the aid of our needle glasses and the microscope, trace most, if not all, of our troubles to minute insect pests, existing and insidiously eating the inner bark until they surround a shoot and cut off the sap communication with the upper part, when it withers and dies. The shrinking of the bark, which is generally noticed at the base of a fruit spur, is the first indication that something is wrong. The shrinking or subsiding of the bark is as natural as it would be for ice on a pond to subside if the water were pumped out. If we take a knife and cut open the infected or diseased part we find the larvæ of insects thickly distributed over the dead space, eating the life out of it, as I will show you presently, also the insects which I believe to be the parents, and also undeveloped eggs thickly distributed on the bark, more especially on the base of bloom buds. As regards some sorts of Apples or other fruits being more subject to their attacks than others, may I not ask why insects should not have their preference for our best flavoured sap, as well as us individuals for the fruit? It is generally admitted that Ribston Pippin Apple is the most attacked, and, with me, Blenheim Orange next. I might go more fully into this question, but time will not allow. 3rd, What is the remedy? I say stamp it out, if possible, by pruning out every bit of dead wood; rub off all loose bark from the stems and boughs—first, I should have mentioned, placing newspapers or something under the trees to catch the rubbish, as this contains, it may be, thousands of insects' eggs and larvæ, which must be carefully collected and burnt. Now apply with a brush, or, to parts that cannot be conveniently got at, with a syringe, a solution of 1 oz. of coal-tar soap to a gallon of warm soft water; this will kill any stray insect in about a minute, as I have tried by experiment. As this is rather strong suds I cannot say whether it would be at all injurious to the trees; but in order to be on the safe side it would be advisable to well syringe with clean water before the suds dry on. If thought advisable a good dressing with limewash, in which a little soot and soft soap is added, may be applied as far as the brush will admit. I may say, as you know, I take much interest in our birds; we have (or rather should have, as Nature provided them, but, unfortunately, they have nearly disappeared from the land) several kinds of woodpeckers, with their long telescope-like tongues which they can insert into every hole and cranny in the bark and fetch out these lurking insect pests. We have a few of those interesting and useful tree-creepers also left, which feed exclusively, I believe, on bark insects. The whole of the tit tribe, and the beautiful golden-crested wrens also take their part in keeping down millions of insects unnoticed by the human eye.

"Mr. B. Harris stated, that having noticed the matter very carefully he felt convinced that insects, and not the gravel, were the cause of canker. Mr. Darby produced what he considered was a different sort of canker. The top part of the tree was all dead, the whole of the buds being taken with the canker. The buds being very sappy the insects preferred them as a depositing place for their eggs. The only thing he felt he could do was to follow Mr. Hiam's advice. Mr. A. Thornton thought that as far as he was concerned the idea as to insects being the cause, and not the effect, was rather new to him, but after hearing the remarks already made, and seeing the evidence produced, he was inclined to think there was something in it. The flow of sap was undoubtedly stopped by the canker, and the insects fed on it, as was seen by the leaders being quite gone. He felt, however, that the sort of tree and the nature of the soil had something to do with it. Mr. W. Thornton expressed a belief that the insects made a choice of the tree. The development of the insect, from the egg to the living animal, was shown under the microscope. The meeting was most interesting and instructive. At the close a hearty vote of thanks was passed to Mr. Hiam for the production of specimens, and to Mr. W. R. John for the use of his microscope."

[With the above matter Mr. Hiam sent us photographs which truly, as he says, represent that Apple-growing is not altogether a theory, but a practice with him. One tree, an over-burdened Cobham, being a favourite haunt of the birds, about forty of which have been reared during a period of six years in an old tea kettle. Our correspondent is worthily engaged in preserving birds that are useful in gardens, and in endeavouring to find

out the cause of canker, and devise means to prevent it. We know that dressing with much stronger insecticides than that recommended will not in all cases prevent the evil; but we shall be glad to learn that it will do so in the case of the trees immediately referred to. Insects are almost invariably found in cankered wood and bark just as they are on decayed roots; but is that sufficient evidence of their being the cause of the decay either below or above ground? Correspondents are quite at liberty to express their opinions on this subject.]

VINE ROOTS.

THERE can be no reason for doubting that the cultivation of Vine roots so that they can be maintained in quantity near the surface of the border is of much importance. When near the surface much more can be done in the way of periodical assistance in the shape of liberal dressings of manure, cow, horse, or artificial, or some of both. This is best done by forking up the surface and applying the artificial manure mixed with the fresh soil which is being added to the border, then a top-dressing of either cow or stable manure. The latter should not be applied in as heavy a dressing as the cow manure; 2 inches of stable dung is quite thick enough, 3 or 4 inches of cow dung may be safely applied.

A thorough watering should be given, and the border be maintained throughout the season in such condition as regards surface moisture as will induce the roots to remain and even come to the surface, where they can be more easily managed and supplied with nourishment, which in due time they will return with interest in the form of a good crop of fruit.

When a border is allowed to get dry near the surface, depend upon

Fig. 27.—*Adiantum ciliatum* (see page 130).

it the roots will descend in search of moisture, and often enter a sub-soil that can afford them little nourishment, though finding more of the moisture they love so well. Vine roots will penetrate walls, go through below pipes, paths, and all sorts of obstacles in order to obtain moisture, therefore it is a great pity when they are denied what they so much require by those whose interest it is to supply their wants.

Hand-watering, especially when the "chief" is not present, are often too superficial. It is astonishing what a quantity of water a border can absorb before it is thoroughly soaked, as it should be where the drainage is good. A hose therefore should be used wherever practicable, the water being allowed to run for some time on one portion of the border, and then the hose shifted along. This can be managed and other work carried on by the man in charge, and a great saving in labour effected. The danger of chilling Vine roots by a too liberal supply of water is enlarged on by some cultivators, but the writer is inclined to think that far more Vines suffer from insufficient water than from excess, always remembering that good drainage is of much importance.

When a border is so situated that the water cannot pass freely away, and more than the soil can take up be given, every effort should be made to remedy the defect or water should be more carefully applied. When top-dressing a border, as many of the roots as possible should be taken up and laid among the new soil, some

of the largest of them being nicked with a knife; they will then send out more young roots to feed on the good viands supplied.

When long fibreless roots are formed some of them should be pruned, so that they will emit numbers of young roots. This is the great advantage of Vines grown on the root-pruning system. Instead of a coil of large roots, which have to be unwound and laid out when a Vine grown on the ordinary system is planted, we have a ball bristling on all sides with short fibry roots, ready to work their way steadily into every portion of the border.

Vine roots, in common with those of many other plants, attach themselves to bricks, stones, pieces of charcoal, &c., though it is not advisable to put too many of these in a border, as the space is better occupied by substances calculated to yield more nourishment. If good fibry loam is to be had, that and a mixture of horn shavings, ground bones, and wood ashes form a capital compost for successfully growing Vines in.

By some it is supposed that lifting Vine roots, subjecting them to a good pruning and relaying them in new soil, is such a hazardous operation that it is better left unattempted, and annual top-dressings are put on borders where there are no roots within 2 feet of the surface. However, the number of those who entertain these ideas is every year growing smaller, and Vine roots are pretty generally considered as capable of being manipulated to an extraordinary extent, and brought entirely under the control of cultivators.

The question of inside v. outside borders has been often discussed, and it must be said that good results have been obtained from both. If, however, I were compelled to choose which I would be restricted to, certainly inside borders would be chosen.

With ample means of watering, drainage as it ought to be, good soil, &c., inside borders seem to have the advantage, and grand results have been obtained from them.

Some who commence Grape-growing, especially when the Vines are in outside borders, commit the mistake of making-up too great a width of border at once. Far better add a little yearly than have a great mass at once, which the roots, when they have not been subjected to the pruning system, run right through without staying to search out the good things provided for them. Root-pruned Vines planted in a narrow border, carefully top-dressed, sufficiently watered, and only allowed an extension of border when it is apparent that they have filled the first portion with numerous fibry roots, are sure to produce better results than Vines with long roots planted in a wide border and allowed to run right through at once.—READER.

HARDY PLANTS AND THEIR SYNONYMS.

YOUR correspondent, "Specialist," who writes on this subject at page 84, will do a great service to gardeners if he can persuade nurserymen to adopt anything like uniformity of names for the plants they send out; and perhaps for specific types no more convenient standard could be adopted than that of the Kew herbarium. At the same time it must be borne in mind that it is not practicable or convenient in horticulture to be limited to the use of botanical specific names. There are multitudes of instances in which the botanical specific type is a comparatively worthless plant, but varieties of it, developed by cultivation, are highly ornamental. This remark applies to not only what are properly called florists' flowers, but also to a very large proportion of other species which have been long in cultivation. On going through any class in the herbarium at Kew we shall find that often a varietal name is recognised there in addition to the specific name. It is perhaps too common for nurserymen to adopt this varietal name as specific, dropping the intermediate or true specific name. As an instance of the confusion caused by this we may particularise such additions as "alpina" or "maritima," so the true *Campanula alpina* is a dwarf plant not unlike a diminutive Canterbury Bell in appearance. I never knew it sent out true to name by any nurseryman except Fröebel of Zurich, and I never knew anyone who could keep it alive in England, though it is perennial, for more than one or two years; but though I have never known *C. barbata* sent out as *C. alpina* we receive several alpine varieties of *C. rotundifolia* and *C. rhomboidea* under the name.

"Specialist" says he writes for those who have not a large collection, and besides that his list might be profitably supplemented: I have a very large collection of hardy plants and their varieties, and with every wish to support and assist "Specialist" in his laudable endeavours to promote correct naming, I must say this, a very large proportion of the names contained in his second column have something to be said in their favour, though I may add that in many instances I know by experience that the plants sent out by those names are not the true varieties to which they properly belong. I will select twelve synonyms taken from this second column to illustrate my meaning, though that number might be very largely increased.

Campanula garganica.—The varieties now classed together under

this name at Kew are so very distinct and differ so much in merit that beginners having small collections would hardly suspect them of being identical. It is excusable, therefore, to distinguish these varieties if only we can get the same variety called by the same name.

C. glomerata.—If "Specialist" will visit Mr. Ware's nursery in July, he will find at least six distinct named varieties of this plant differing in size and colour, including the three names specified. All these varietal names have some authority. I have all Ware's varieties, and they keep their distinct character. The greatest favourite amongst them is the one usually sold as "speciosa," which has lavender-coloured flowers.

C. latifolia.—I can hardly think that any respectable nurseryman ever sold this under the name of *C. Van Houttei*, a very distinct hybrid, of which *C. latifolia* is not even one of the parents. *C. macrantha*, however, is a decided improvement of cultivation on the typical native *C. latifolia*. I grow plenty of both.

C. persicifolia.—There are many very distinct forms of this, which must be distinguished by name unless we are to see them in flower before we buy them. For instance, the name *coronata* is given to varieties having saucer-like collars beneath the bells, a peculiarity which Canterbury Bells also have.

C. fragilis.—The variety *Barrellieri* is distinct from the type, being stronger in growth and having hairy leaves. It is also called *C. fragilis* var. *hirsuta*, and I had both these names for it from the Kew herbarium itself. There are white varieties of both these, but they are very hard to keep alive.

C. Porthenschlagiana.—The authorities differ so much between this name and *C. muralis* for the same plant that at the Kew herbarium both names are recognised, the names of the authors which adopt each being appended.

Enothera biennis var. *Lamarchiana* is a cultivated variety having flowers twice as large and a habit twice as branching as those of the type, which need never be grown beside it.

Æ. fruticosa.—Though I never could make out the alleged distinctions between the dwarf forms of this and *Æ. Fraseri*, the variety *Æ. Youngi* is very distinct and superior as a garden plant. I will with pleasure send "Specialist" plants of both to flower and compare if he will write to ask for them.

Papaver alpinum.—This is quite distinct from *P. nudicaule* from a gardener's point of view. It is smaller both in flower and leaf. The two hybridise readily, and the progeny seem to run together.

Saxifraga ligulata.—This is earlier in flower, smaller in growth, more free in flowering, and altogether superior than *S. crassifolia*. Unfortunately it is not hardy in cold gardens, whilst *crassifolia* is hardy everywhere.

Trollius asiaticus.—This fine hardy plant, which I grow in abundance, has its flowers as open as those of *Caltha palustris*. The colour is orange-yellow. Those of *Fortunei*, syn. *japonicus*, are far larger and more globular, and are always killed with me by the east winds of spring. The two are quite distinct for the gardener.

Trollius europæus.—In its cultivated form this varies so remarkably in size, cuttings of leaf, and colour, that we must have distinctive names to know what we mean in speaking of the varieties. These examples might easily be doubled or trebled in number from the list in question; but I hope I have said enough to justify nurserymen in not confining themselves to typical specific names in enumerating the treasures of their gardens. I do not question that reform in names is needed to secure uniformity; still, botanical nomenclature can never be final. I notice that in the "Genera Plantarum," which must long continue a standard authority, that the number of described species in many genera is reduced by half; but botanists will never agree as to the exact amount of divergence which is to constitute a species, and intermediate forms will ever be turning up to fill gaps between supposed differences. Anyone who collects and grows from seed such a genus as *Campanula*, or *Thalictrum*, or *Veronica*, or *Aquilegia* will soon find how difficult it is to draw hard-and-fast lines, and how excusable it is to give names to distinct varieties.—C. WOLLEY DOD, *Llandudno*.

THE VINEGAR PLANT.

A CORRESPONDENT of the Journal, "H. T. H.," wishes to know where he can buy a Vinegar Plant. If he is not in urgent need of it he can make or develop one for himself, and the process is interesting. It is as follows:—Dissolve in three quarts of water half a pound of treacle and a quarter of a pound of sugar. It is best done over the fire, but the liquid must neither burn nor boil; then place it in a jar and cover it up closely, keeping it afterwards in a warm room for about six weeks, when the fungus or Vinegar Plant will appear on the surface. A plant thus obtained may be cut into a number of pieces, and each becomes a separate plant, with the power of turning to vinegar any sweet solution upon which it is floated.—J. R. S. CLIFFORD.

THE flabby piece of fungus which housewives used to treasure as a

Vinegar Plant has not the power of itself of converting alcohol into vinegar, but is a disease similar, say, to the growth of lichens on an Apple tree, and consequently highly undesirable.

The acetous fermentation is brought about by a special ferment called *Mycoderma aceti*, somewhat like the cells of yeast in appearance, only much smaller. The so-called Vinegar Plant may have this negative virtue—that is, it is difficult to imagine it to exist without enclosing some of the true ferment in its leathery embrace.

My advice to "H. T. H." is that he use his cider as such, and leave vinegar-making to those who know more about it; but if he will try his hand, let him add a few gallons of sound vinegar to his cider, half fill the cask with the mixture, and leave the bung out. The added vinegar will almost certainly carry germs of *Mycoderma aceti* with it, and the acidity so brought about will hinder the growth of an analogous but detrimental ferment called *Mycoderma vini*, which affects cider.—A VINEGAR MAKER.

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 12TH.

THE contributions from nurserymen and gentlemen were so numerous on this occasion that quite an exhibition was provided, Cyclamens and Primulas being very largely represented. Orchids, too, were very attractive, and with Camellias, Roses, Hyacinths, Tulips, and miscellaneous plants, rendered the meeting a most interesting one. Nearly all the members of the Committees were present.

FRUIT COMMITTEE.—Harry J. Veitch, Esq., in the chair. Present—Messrs. J. Lee, Phillip Crowley, J. Ellam, R. D. Blackmore, G. Bunyard, W. Denning, C. Silverlock, J. E. Lane, James Smith, John Burnett, H. W. Sutton, J. C. Mundell, J. Roberts, S. Lyon, Sidney Ford, G. Goldsmith, and G. Paul. The Apple, Perkins' A1, exhibited by Messrs. T. Perkins & Sons, Northampton, at the last meeting, was cooked and tested by Mr. Barron at the request of the Committee. Some were baked and others boiled in dumplings, and in both cases they turned out well, the substance being well retained, with the pulp quite tender, yet somewhat dry and wanting in briskness, requiring very little sugar. It was considered very good, and was awarded a first-class certificate. A bronze medal was awarded to Messrs. Lane & Son, Berkhamstead for a collection of sixty dishes of fine Apples, Lane's Prince Albert being in excellent condition; Hanwell Souring, Norfolk Beefing. Mère de Ménage, Annie Elizabeth, Hoary Morning, Galloway Pippin, and Cox's Orange Pippin being well shown. A bronze medal was also awarded to Mr. G. Goldsmith, Hollandsbury, Tunbridge, for a collection of fifty dishes of Apples, some of which were exceedingly fine, especially noteworthy being Blenheim Pippin, Lord Derby, Hollandbury, Cox's Pomona, Golden Noble, Hall Door, and Winter Queening. Several dishes of Apples were also shown from Chiswick. Mr. T. Bonsall, The Gardens, Campsmead, Doncaster, sent samples of a seedling Onion which was not considered of special merit, and Mr. Robert Doe, The Gardens, Rufford Abbey, Notts, sent a seedling Apple that was also passed. John Lee, Esq., sent a fruit of a large Orange from Java, which was very juicy and of good flavour. Mr. S. Ford, Leonardslee, sent two dishes of the bright red Apple Margaret Henrietta. The Cranston Nursery Company sent samples of Apple Herefordshire Beefing. Mr. Turner, Slough, showed tubers of Schoolmaster Potato, large and even.

FLORAL COMMITTEE.—Section A.—Mr. John Fraser in the chair. Present—Messrs. C. Hill, J. O'Brien, J. Dominy, H. Ballantine, J. Hudson, G. F. Wilson, J. Woodbridge, H. Herbst, H. Williams, T. Moore, Rev. G. Henslow, and Dr. Masters. Section B.—Shirley Hibberd, Esq., in the chair. Present—Messrs. Bennett, W. Bealby, J. Llewellyn, J. Douglas, J. James, J. Child, G. Duffield, D. Lathbury, H. Turner, W. B. Kellock, and H. Cannell. Messrs. Veitch & Sons, Chelsea, contributed very largely to the interest and beauty of the display, a considerable space being occupied with groups of Cyclamens, Primulas, and miscellaneous plants. About 150 Cyclamens were shown in extremely fine condition, with large handsomely marbled leaves and mauve, white, crimson, or parti-coloured blooms. The plants were mostly in 48-size pots, and bore twenty to thirty flowers. The Primulas were white and crimson, arranged in alternate rows; the flowers large, of good substance, and in compact heads well above the foliage. A small group of the charming *Freesia refracta alba* bearing abundance of its pure white exquisitely fragrant blooms was much admired. This is a useful and beautiful plant, and well worth the attention of gardeners, it was figured and described in this Journal, page 171, vol. ii. Several plants of *Allium neapolitanum*, with neat umbels of white flowers, were shown, and proved the value of the plant for early flowering. It was also figured in this Journal, page 451, vol. vi. Among other notable plants were the following:—*Pinguicula hirtifolia*, a diminutive plant about an inch high and across, with small flowers, white in the throat, edged with purple. This was referred to the Scientific Committee. *Rhododendron Curtisii luteolum*, a Sumatran plant of rather straggling habit, but with neat bell-shaped dull yellow flowers 1 inch in diameter; and *Dendrobium macrophyllum* var. *Burkei*, a distinct variety, flowers large, sepals and petals white, the lip tinged with pale purplish mauve at the base. A vote of thanks was accorded for a large pan of Comte Brazzi's double white Neapolitan Violets, the blooms being of great size. A silver-gilt Banksian medal was awarded.

Mr. J. James, Woodside, Farnham Royal, Slough, staged a group of 100 dwarf freely flowered Primulas, comprising crimson, pink, white, and a rich bright red, a wonderful colour. Several seedling Cinerarias of great merit were shown, and some were certificated and are described below. Mr. R. Clarke, Twickenham, was awarded a silver Banksian medal for a group of 120 healthy Cyclamens. Rose, crimson, pink, white, and crimson-tipped were the colours represented. The flowers were all remarkable for their great size, the breadth of the petals, and the purity of the colours. Messrs. Barr & Son, King Street, Covent Garden, sent a collection of hardy flowers, chiefly Narcissuses and Irises. The early *Narcissus pallidus præcox*, with clear yellow crown and pale yellow sepals and petals, was very attractive, and the purplish mauve delicately tinted *Iris stylosa* was equally beautiful, together with flowers of the fragrant *Iris reticulata* var. *Krelagei*. Mr. Child, gardener to J. Bell, Esq., Garbrand Hall, Ewell, showed several pure white and crimson Primulas. The flowers were large and of great substance.

A large group of Cyclamens, comprising over 150 plants, was contributed

by Mr. J. Wiggins, gardener to W. Clay, Esq., Grove Road, Kingston. A number of varieties was represented, and several specimens were in extremely fine condition, bearing three or four dozen flowers in 52-size pots. A cultural commendation was awarded for one extraordinary specimen of a white *Cyclamen*, General Gordon, in a 9-inch pot. It was more than 2 feet in diameter, with abundant vigorous foliage, and over 300 flowers and buds. A good collection of *Cinerarias* also added to the interest of Mr. Wiggins's display. A silver-gilt Banksian medal was adjudged for these collections. Mr. J. Bennett, Shepperton, sent a box of Tea Rose William Francis Bennett, the variety which has become so great a favourite in Covent Garden Market and in America. In the bud or half-opened state it is very beautiful, of a clear rich rosy purple hue, the foliage being small, neat, and bright green. A cultural commendation was awarded to Mr. R. Aldous, gardener to G. Heriot, Esq., Cholmondeley Park, Highgate, for a plant of *Vanda Cathcartii*, with eleven flowers on three spikes. A vote of thanks was accorded to Mr. A. Waterer, Knap Hill, Woking, for a fine plant of *Andromeda japonica*, 3 feet high and as much in diameter, profusely flowered. Mr. Waterer also contributed a most tastefully arranged group of Primroses, margined with bunches of red and white Heaths. A great number of varieties was represented amongst the Primroses, crimson, maroon, yellow, white, and purple were finely shown. A silver Banksian medal was awarded for the group. Eight boxes of Camellias were staged by Messrs. Wm. Paul & Son, Waltham Cross, Herts. Marchioness of Exeter was finely represented, the deep rose blooms being large and well formed. The delicate rose L'Avenir, the rich red Eximia, the dark red Lecana superba, and the white Fimbriata and alba plena were the leading varieties. A silver Banksian medal was awarded.

Mr. B. S. Williams, Upper Holloway, had an extensive and bright display, occupying a considerable space on one side of the conservatory. *Cyclamens* were shown in fine condition. A group of sixty well grown Hyacinths and Tulips were much admired, the spikes of the former being of great size and colours clear. *Primulas fimbriata rubra* and *alba* were staged in good condition. A silver Banksian medal was awarded. Mr. H. B. Smith, Ealing, had a good group of *Cyclamens*, the white varieties being extremely fine and free, and a red variety named Crimson King was remarkable for the rich colour of the blooms. Mr. Edwards of Hillingdon also sent several seedling *Cyclamens*. Messrs. Carter & Co., High Holborn, sent a dozen baskets of *Primulas* representing the varieties Holborn Blue, Holborn White, Holborn Vermilion, Holborn Ruby, Magenta, Gold-leaf, Pearl Salmon, and several others, the colour being mostly very good. A neat bluish mauve *Polyanthus* named Amethyst was shown by the same firm, and a vote of thanks was accorded for the collection. A vote of thanks was awarded to Mr. O'Brien, Harrow-on-the-Hill, for a plant of *Davallia Mariesi* on a neat stand, the rhizomes having grown closely together in a hall-like form. Messrs. Stuart & Mein, Kelso, N.B., sent a plant of *Spiraea confusa* with numerous small umbels of neat white flowers. Mr. Wells, Fern Hill, Windsor Forest, showed a basket of a large single dark blue Violet named Wellsiana, the blooms being nearly an inch in diameter. A vote of thanks was accorded to Mr. J. Walker, Thame, for a freely fruited plant of *Fuchsia procumbens*, several large pots of *Lachenalias*, and flowers of *Tritoma uvaria*. Mr. E. Wilson, gardener to H. M. Pollett, Esq., Fernside, Bickley, was accorded a vote of thanks for a collection of Orchids, comprising *Odontoglossum Rossi majus* and *rubescens* and *Phalaenopsis Stuartiana punctatissima*, the last being a finely spotted form. Mr. West, gardener to Major Lendy, Sunbury House, Sunbury, was awarded a cultural commendation for a healthy plant of *Cattleya Percivaliana* var. *citrina*, a very distinct form with a broad lip, yellow in the throat and rich crimson at the tip.

Messrs. H. Cannell & Sons, Swanley, had a group of *Primulas* comprising some well-grown plants, and such fine varieties as The Queen, bluish white; Swanley Giant, Swanley Red, and Princess Beatrice, together with plants of the old Double White, and a fine single variety which was certificated. Votes of thanks were accorded for this collection and a box of large brilliantly coloured *Cineraria* blooms. Mr. H. Heims, gardener to F. A. Philbrick, Esq., Q.C., Oldfield, Bickley, showed two fine plants of *Lælia harpophylla* with over twenty flowers each. A cultural commendation was awarded. *Odontoglossum crispum aureum* was represented by a plant bearing a spike of sixteen flowers, and a vote of thanks was accorded for some fine *Cattleya* flowers, varieties of *C. Trianae*, and a good *Angiæcum sesquipedale*. Mr. J. W. Cummins, gardener to A. H. Smee, Esq., Wallington, sent a plant of *Comparettia macropleuron*, bearing a spike of eight large flowers. A vote of thanks was accorded to Mr. J. Hodges, gardener to Edwin Wright, Esq., Gravelly Hill near Birmingham, for flowers of a fine *Odontoglossum* named *Alexandrae alium superbum*, *Calanthe vestita lutea alba majus*, and *Lælia alhida*.

First-class certificates were awarded for the following:—

Cattleya Percivaliana var. *alba* (R. P. Percival, Esq.).—This differs only from the type in the sepals and petals being pure white, the lip being rich yellow in the throat.

Lælia anceps Williamsiana (F. Sander & Co.).—A very distinct variety with white sepals and petals; the lip also white, but yellow in the throat and streaked with purple. The flower is 4 inches in diameter.

Odontoglossum Pollettianum (Mr. E. Wilson, gardener to H. M. Pollett, Esq., Bickley).—A hybrid of great beauty, somewhat like a large *O. odoratum* or *O. gloriosum*, with large chocolate spots and blotches.

Oncidium Jonesianum (Mr. G. W. Cummins, gardener to A. H. Smee, Esq., Wallington).—A distinct species with terete leaves 8 to 12 inches long. Flowers 2 inches across; sepals and petals greenish with reddish brown spots; the lip white, yellow at the base, and a few red spots.

Oncidium anthocrene (Messrs. F. Sander & Co.).—Flowers 2½ inches across; sepals and petals narrow, curled and undulated, brown, barred at the base; the lip small, whitish at the tip. The panicles are from 1 to 2 feet long, with short branches bearing two or three flowers. The pseudo-bulbs are 3 to 4 inches long, flat and fluted, the leaves 12 to 18 inches long and 2 inches broad.

Parrotia persica (W. Paul & Son).—Flowering branches of this shrub were shown, the chief beauty of which was the abundant red anthers in dense clusters surrounded by brown scales. The leaves assume some remarkably rich and varied tints in the autumn, and it is then very attractive.

Saxifraga Burseriana (Carter).—One of the dwarf tufted type of *Saxifragas*, with glaucous needle-like leaves and white flowers half an inch across and borne on stalks 2 inches high.

Cyclamen Dame Blanche (H. B. Smith).—An exceedingly fine variety, pure white, the petals 2 inches long and 1 inch broad, of great substance.

Cyclamen giganteum delicatum (Edwards).—Flower of great substance, the petals an inch broad and 1½ long, pure white, tinged with purple at the throat.

Primula Emperor.—Flower 2½ inches in diameter, fimbriated at the margin, of a distinct rosy red colour, and yellow centre. A grand flower, one of the finest that has yet been certificated.

Cineraria Lottie Williams (James).—Very distinct, finely formed flowers, deep maroon purple, with ring of light crimson near the centre, the disk white.

Cineraria Great Eastern (James).—A grand flower, 3 inches in diameter; the petals broad, of great substance, and very bright crimson in colour. A magnificent variety.

Epacris Diadem (Veitch).—A handsome variety; flowers deep rose, three-quarters of an inch long, and closely set on the upper portions of the branches.

Epacris The Premier (Veitch).—Similar to the above in size of flower, but of a softer delicate pink hue; the limb of the corolla is rather broader, and the flowers more closely set.

Jambosa acida (Williams).—The specimen shown was a small tree 8 or 9 feet high. The leaves are 2 feet long and 1 broad, elliptical, deeply ribbed, the older ones dark green, the young ones of a rich purplish red. The certificate was granted provisionally upon the name being correct.

Narcissus pallidus præcox (Barr & Son).—An extremely early variety flowering in January. The crown is 1½ inch deep and 1 inch across at the mouth, clear yellow, the margin irregularly cut. The sepals and petals are 1½ inch long, paler than the crown, nearly white, and spreading. This was certificated upon the understanding that it had been grown out of doors.

KITCHEN GARDEN.

Parsley.—This is one of the most important of all kitchen garden occupants. In every kitchen of any importance it is in daily demand throughout the whole year, and any blank in the supply often causes great inconvenience to the gardener and cook. Last year's plants are not so luxurious as they were in the autumn, as many of their most robust leaves have been gathered or died away, and where they are withered and useless they should be removed, the ground around the plants being stirred with the Dutch hoe. This will induce the plants to make fresh growth, which will be very acceptable until the spring-sown crops are ready, but old plants sown throw up flower stems when the mild weather comes, and then the produce is inferior. The gatherings from spring sowings are always best in summer, and a small quantity of seed should be sown at once. Carters' Fern-leaved is a superb variety for garnishing, and Myatt's is an old, well-known, and valuable sort. The ground for the reception of the seed should be well manured and quite free from all grubs. The seed may be sown in rows about 1 foot apart. Where seed was sown late last autumn, and the plants are now only about an inch high and very close together, a number of them should be drawn out and planted elsewhere. Soot, lime, and salt applied to the soil in moderate quantities are good grub-preventives.

Autumn-sown Onions.—These now in beds and rows close together should be thinned and planted in the soil prepared for them as advised a fortnight ago. They delight in rich soil and a sunny position. We plant thousands at this time in rows 1 foot apart, and 6 inches from plant to plant. They are dibbled in without much attention, as they are hard to kill and easily grown. A good patch of the Onions should be found in every well-managed kitchen garden.

Spring Onions.—A few rows of these should be sown, Webb's Banbury or Suttons' Reading being good varieties. If the ground is deeply dug and highly manured, and the seed put in when the soil is in fine order, the bulbs will stand a good chance of becoming splendid exhibition specimens before the month of August. We always secure the largest spring Onions from seed sown about this time.

Peas.—A general sowing of William I. and Advancer or First Crop, Sangster's No. 1, and Daniel o'Rourke may safely be made now in the open quarters in all gardens. Drills 4 inches deep and 5 feet apart will suit all the varieties named.

Parsnips.—In favourable localities the main crop of these may be got in on the first favourable opportunity. The soil best suited for their finest development is a deep, free, and open substance, rich, but free from fresh manure recently introduced. The rows must be from 15 to 18 inches apart, and The Student should be grown for quality, and Carters' Maltese variety for size and exhibition.

Rhubarb and Seakale.—Where new plantations of these are contemplated they can be proceeded with at once, as the growths are pushing up now, and will be more liable to be checked by-and-by.

Shallots.—These should be sorted and planted, only sound bulbs being used. They may be placed in rows 6 or 8 inches apart each way, and each set should be almost covered with soil. Where the latter is heavy a little sand put around each bulb is a great assistance to growth.

Asparagus.—All operations connected with this must be finished quickly. It is not yet time to sow or plant, but all top-dressing and

enriching the soil in connection with plantations from which spring cutting has to be done should have immediate attention. Top-dressings of half-decayed manure, soot, salt, and guano are of the greatest benefit to Asparagus, especially in poor soils.

Mushroom Beds.—Those to produce crops in April and May should be formed at once. A cool shed we find the best situation for them. Old beds which show no energy and are dry and lifeless may be revived, as a rule, by giving them a thorough supply of water heated to 90°, covering them immediately afterwards with a thick coating of dry hay or straw.

Celery.—A pinch of seed may be sown in a 6-inch pot to produce a few scores of early plants, which are often required, and are valuable before the main sowings come in. The seed will germinate and the plants grow freely in any place where the temperature is 60°.

Cucumber, Tomato, Vegetable Marrow, and Egg Plant seeds may all be sown singly or in small groups in pots. Good soil and a gentle heat suits them all. Plenty of light will produce robust fruitful plants, but none of them must as yet experience any check at the roots, and the utmost care should be taken that all young plants have timely attention in being potted or planted out.

FRUIT-FORCING.

PEACHES AND NECTARINES.—*Earliest House.*—The fruit in this structure having commenced swelling freely, and the set being thick, the thinning should go on gradually, removing the smallest and worst placed until there are few more retained than will be required for the crop, about one fruit to every square foot of trellis covered by the trees. With the trees in good health and proper treatment there is no need to fear any of it not stoning safely, yet it may be advisable to leave a few more fruits to meet casualties until the stoning is effected, when they must be at once removed.

Disbudding.—Daily attention is necessary with trees subjected to early forcing. Begin with the gross foreright shoots, as these would take from those at the base, which it is desirable to encourage, so that strong bearing shoots may be secured for another season. Remove those not required for extension a few at a time, stopping those retained for attracting the sap to the fruit about the third leaf, and these must be on a level with or above the fruit. It is advisable to remove those on the under side of the trellis first, and then commence with those on the upper, from which the shoots for next season's fruiting should be selected. Avoid giving a check to the roots, as this may cause the fruit to swell imperfectly, if not to fall.

Feeding.—If fermenting materials have been used in the house they will now be cooled, or should be allowed to do so, as there is danger of the foliage being damaged if fresh material is introduced so as to give off a large amount of ammonia vapour. The materials, if any have been employed, may now be spread over the surface of the border as a mulch, or well-worked horse manure introduced to the extent of 2 or 3 inches thickness, and the borders and paths may be sprinkled two or three times a week with liquid manure. Liquid manure may be given whenever water is required in the case of trees that are weak from age or hard forcing, but it must not be given to trees in a vigorous condition until a later stage. If the roots are outside they must be well protected with litter or Oak leaves, with shutters to throw off cold rains or snow.

Syringing.—Do this twice a day, in order that every part of the old wood and foliage may be thoroughly cleaned with water, which ought to be soft, clear, and a few degrees warmer than the house. If the syringing be properly attended to there will not be any red spider. In dull weather syringing must be lessened, and the afternoon syringing must always be done sufficiently early to allow of the tree becoming fairly dry before dark.

Temperature.—Do not exceed a temperature of 55° at night except on mild nights, and on severe nights the temperature may fall to 50° in the morning, and from fire heat in the daytime allow an advance of 5° to 10°, running up to 80° from sun heat, with a circulation of air, commencing to ventilate at 65°, and close at 70° with a copious syringing.

Succession Houses.—The trees in the house started early in the year are in splendid condition, blooming strongly, and must have attention daily after the pollen becomes ripe for dispersion. The weather is so mild that bees if at all near will find the blossoms out, and do the work of impregnation far better than any brushing or shaking. Although we do not advise syringing the trees when in flower, we always sprinkle the floors, borders, &c., in the morning and early afternoon unless the weather be damp and dull, when it is of course omitted.

Late Houses.—The trees are not so forward as was at one time anticipated, but they are looking well and promise abundant bloom. Where the trees are at all weakly draw the hand the reverse way of the growth on the under side of the shoots after the buds are sufficiently swelled, so as to remove those on the under side of the trellis. Look to the roots of trees in inside borders, and give a thorough soaking of water if there be the least evidence of dryness. Give abundance of air, and so retard the blooming as much as possible.

Pines.—Plants that have been wintered in 7 or 8-inch pots should be placed in their largest pots before they are weakened by the roots becoming too much matted together. As the operation must be carried out shortly a sufficient quantity of potting material should be housed at once, in order that it may become drier and in a fit state for breaking up, which should be done by hand, tearing the sods into pieces with the hands, discarding the small and retaining the fibrous portion. Pots

11 inches in diameter will be suitable for Queens, and 12-inch pots for the more robust-growing varieties. Let the soil in potting be firmly rammed round the old balls of soil, water at once to settle it, and plunge the pots in a brisk bottom heat of about 90° or 95°, keeping the top heat 60° at night, 65° by day from fire heat, and from 70° to 80° from sun heat. It is not advisable to encourage much top growth until external influences are more favourable from the increased light. Make the needful provisions for potting suckers which are to be started next month. If space will admit it will be advisable not to remove the suckers from the stools until they are wanted for starting, as there is a decided advantage in having them fresh.

Fruiting Department.—Early-started fruit will be well advanced for flowering. Avoid wetting the flowers, as the moisture which forms at the base of the fruits results in the discoloration which sometimes exists about the base of the pips. Watering must be attended to as necessary, never water until it is needed, and then apply it liberally. Maintain a steady temperature of 70° to 75° at night, 75° to 80° in the daytime, 80° to 90° with sunshine, ventilate at 80°, and close at 85° with a moderate amount of moisture obtained by damping available surfaces.

PLANT HOUSES.

Odontoglossums.—Without further delay these plants should be repotted, if not already done. Remove carefully from amongst the roots the whole of the decomposed material, and wash their roots in tepid water. The plants may then be repotted in the same or larger pots, according to the quantity or quality of their roots. The pots to be used should be three parts filled with crocks or charcoal, and then covered with a layer of moss. The compost should consist of one-third peat fibre and the remainder living sphagnum moss and lumps of charcoal, which should be carefully laid amongst the roots, and the plants when finished well elevated above the rim of the pots and surfaced with a layer of living moss only. After repotting every attention should be given to watering, damping amongst the pots, and syringing the moss, so as to encourage it to commence growth as rapidly as possible.

Cypripediums.—The majority of these may now be repotted, but in turning them out of their pots or pans be careful not to injure their roots, for they generally cling tenaciously to the sides of the pots in which they are growing. In many cases it is necessary to break the pots in which they are growing, and this had much better be done than injure their roots in trying to turn them out without. All the smaller plants are repotted annually, while those of a larger size are only operated upon every second year. From the latter pick away all the surface material that it is possible to remove and supply fresh, while from the smaller specimens remove the whole. Use for these plants equal parts of peat fibre and sphagnum moss, with lumps of charcoal or pieces of crocks added. These plants while in active growth require abundance of water, and the material about their roots soon becomes decomposed.

Dendrobiums.—Some of the earliest plants of *D. nobile*, *D. heterocarpum*, *D. Wardianum*, and others have just commenced to form roots from the young growths, and should be repotted or top-dressed without further delay. These do well either in pots or baskets suspended from the roof of the stove; the first is useful in pots for removal to the conservatory when in flower. If repotted last year they need only be top-dressed at the present time, but if not turn them out of their pots, and pick away all decomposed material. Do not disturb portions of charcoal or crocks to which their roots adhere. Replace them in the same or larger pots in a mixture of peat fibre three parts to one of moss, with charcoal used liberally in lumps. The other varieties may have if grown in baskets all the material possible removed from them and fresh supplied; for these the moss should predominate. Syringing, with an occasional soaking of water, will be ample until the roots are working freely, when abundance of water should be given.

Calanthes.—Those who retarded a batch of these as late as possible before starting, and then brought them forward in a temperature of about 55° after they commenced showing their flower spikes, will find them invaluable when the main stock of these are over. *C. v. Turnerii* is the best late variety, but other forms of *C. vestita*, as well as *C. Veitchii*, may by careful and judicious treatment be had in flower at the present time. Those that have flowered may be turned out of their pots and stored amongst sand or moss in boxes in any warm shed where the temperature will not fall below 50°.

Gardenias.—These will now be showing and producing flowers in quantity—that is, those that have been forwarded in brisk heat. Give weak stimulants in the form of liquid manure every time watering is done; or, better still, sprinkle on the surface of the soil some artificial manure. If fine flowers are required remove the young growths from the base as soon as they are formed. These when large enough make the best of cuttings that can be obtained, and will root quickly in heat under a bellglass, and if an increase in the stock is required the sooner they are rooted the better. Where the stock for spring flowering is grown annually from cuttings a good number should now be rooted. Plants rooted last August, and now bushy specimens in 4-inch pots, may be placed in 6-inch pots. These plants can be grown successfully in either good loam or peat; but a mixture of both is preferred—three parts of the former to one of the latter—with a liberal quantity of sand added and a little bone meal. A little prepared cow manure rubbed through a fine sieve is also beneficial. After potting, if practicable, give bottom heat for a time until the roots are growing again freely.

THE BEE-KEEPER.

THE MILD WEATHER AND BEES.

THIS current winter has been perhaps the most open for many years. Bees have consequently been more or less on the move in all parts of the country; not so much so in our own apiary as with those whose hives stand in warm sunny places. Where bees have been unusually active the mortality must have been very great in winter. Bee-keepers as a rule are not careful enough to shade the entrances to hives, and do all they can to keep the bees in. A flight now and then during the winter is most conducive to health, and in most winters opportunities for this occur after some three or four weeks of captivity. But this season has given by far too many of such opportunities, and the consequence is that during sunny weather bees have taken longer flights than usual, and many have been out never to return. During the winter months birds are much more ready to snap up the wanderers; less food of other sort is available. Tomtits are especially voracious at this time of the year, and we have watched them keeping a good look-out before hives for their prey. Sparrows do not seem to seek for bees as food until nesting time, when a pair of sparrows will, according to a calculation we once made, after carefully watched how often the old birds returned for a bee, take a good-sized swarm during the time they are feeding up a nest of young ones. The sparrow, like the tomtit, carefully but very dexterously first extracts the sting before giving the insect to its young or eating it itself. Thus the mild season which furnishes food for the birds thins the hive. Much food is also consumed where bees get out often when they should be clustering at rest.

Our hives are all in a bee house. During the working season a 9-inch flap hung on butts stands wide open all round the house, and the bees have free entrance to their hives. These flaps are now all closed, and have been so since October. The bees are in partial darkness; their exit to the open air is only now through slits in the flap, and the sun has to be out some time before they feel its influence. Thus they are called out, not by sudden bursts of sunshine, but by a general rise of temperature with sunshine combined. A hive which is so arranged as to indicate on the disc of a Salter's balance the weight of loss or gain tells us that from the 9th of October last until now 9½ lbs. of food have been consumed. This hive is constructed exactly similar to all the other hives we use, and which have been fully described and illustrated in the Journal, only it has double glass slides and front and back. The bees are passing the winter in this hive in a perfectly healthy condition. The bars are covered with quilt and box of chaff, and the glass is perfectly dry and clean, showing that all excessive moisture passes off through the top coverings.

From what we have this winter seen of our bees and their condition we are more and more convinced that a good roomy shed, such as we have made, is a much better situation for stocks during winter than the open. They would be some degrees warmer than in the open should very sharp frost set in, and they are at the same time less influenced by the kind of muggy-warm weather we have been experiencing during the last three months; they will eat less, and there will be less mortality. We do not say that a bee-house is the best place for bees everywhere, but in an open, exposed, windy, and damp locality we would certainly when possible put them under cover.—P. H. P.

A METHOD TO CURE FOUL BROOD.

WE have then to set ourselves this problem: "To find a method at once rapid and economical, by the aid of which the bees may introduce into the nourishment of the larvæ a minute quantity of acid in order to constantly neutralise the germs of the disease, without, however, in any way disturbing the natural order or their daily labours."

The experiences of this year seem conclusive, and make me hope for a complete success in the future. To obtain this result I have kept the water reservoir where my bees go to get their supply charged with water mixed with salicylic acid. I dissolved 50 grammes of salicylic acid in 400 grammes of alcohol, and for each litre of water I added 10 grammes of the above solution. This dose is about double that generally recommended to be used in syrup. The consumption of water has been, on the average, 3 to 4 litres. On certain days in cold weather it seemed to me that the water had a gelatinous appearance, but the bees sucked up the moisture from the cloth covering the tank, and all seemed to go well. This treatment lasted for seven weeks, but in reality the greatest honey flow will prevent the bees going to the reservoir for at least ten days, and they return to it only when the flow of honey slackens.

I had in the spring six colonies more or less affected. Three of these I treated by the first-described method. I left the other three for experiment's sake in the condition they were in.

After seven weeks of this general "water cure" I examined the six

colonies very minutely, every frame of brood being carried into a warm room in the order that they held in the hives.

The other colonies in the apiary were all examined frame by frame, and none appeared attacked, the disease having probably been killed everywhere immediately it showed itself.

Egg-laying in spring is always very regular, because the queen finds plenty of room free of honey; one can then easily follow its progress at this period.

In examining the combs of brood of the three colonies to which I had given no special treatment, I remarked at first a large quantity of brood on the first frame diseased. This comb was the one on which the queen commenced her spring laying. The two other combs, to the right and left of this one, were also sadly diseased; the fourth and fifth commenced to be much less so: in their centres many bees had come out of the cells, but there were still a certain number of cells isolated that were diseased. In the circle of brood (sealed) surrounding the portion empty of brood, I met with very little of the disease, and at last the combs, furthest out from the frame on which the queen commenced her spring laying, did not appear to contain a single diseased cell.

The disease, instead of going on increasing, as is usual, had diminished progressively. I took away all infected combs from these three hives, and commenced feeding them with acidulated syrup. The three other colonies transferred to new hives appeared in good condition. At the moment of writing, my apiary appears cured just by this retrograde action of the disease, and I have every hope that it will continue the same until autumn. I will continue the "water cure" right up to the end of the season, and propose to continue this treatment in the surrounding country until the disease has disappeared from my neighbourhood.—GEORGES DE LAYENS (in *American Bee Journal*).

TRADE CATALOGUES RECEIVED.

Walter Ford, Pamber, Basingstoke.—*Lists of Flower and Vegetable Seeds.*
George White, Carriagehill House, Paisley.—*Catalogue of Florists' Flowers and Herbaceous Plants.*

James Dickson & Sons, 108, Eastgate Street, Chester.—*Catalogue of Flower and Vegetable Seeds.*

W. Lovell & Son, Driffield, Yorkshire.—*List of Strawberry Plants.*

Richard Dean, Ranelagh Road, Ealing.—*Catalogue of New and Choice Florists' Flowers.*

Leveque et Fils, Ivry-sur-Seine.—*List of Roses.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Back Numbers (*S. B.*).—We have received your letter, and the subject has been attended to.

Lycaste Skinneri alba (*J. H. S.*).—The plant you send under this name is *Lycaste lanipes*, which differs greatly from the white variety of *L. Skinneri*, and is much inferior to it both in beauty and value. Small plants of the latter have been sold for twenty guineas quite recently, but half a guinea will purchase a good example of *L. lanipes*. *L. Skinneri alba* has flowers exactly like the ordinary red or pink type, the sepals and petals broad and thick, but pure white. It is easily recognised.

Select *Camellias* (*J. H.*).—The following are free and useful:—*Alba plena*, white, invaluable; *imbricata*, deep crimson; *Queen of Roses*, pink; and *Cup of Beauty*, white and pink. *Comte Brazzi Violet* is white and very full. We do not know a blue one with that name.

Ribbed Glass (*C. B.*).—We have had no experience with the glass of which you have sent a sample, but we do not see why it should not answer for a greenhouse or frame in which plants are to be cultivated. If we had a quantity we should not hesitate trying it, even if a little shading had to be resorted to in very hot weather.

Gardening Appointment (*G. B.*).—There are at present no grounds for your supposition, and we fear you do not read very attentively. See p. 82 of our issue of the 11th ult.

Kidney Beans in Pots (*A. M.*).—In order to be able to gather Beans early in April no time should be lost in sowing seed. You will find Osborn's Forcing a desirable variety, as in addition to being quick-growing and

prolific it is unsurpassed in quality. If a longer-podded variety is preferred Canadian Wonder is suitable. Either 9 or 10-inch pots may be employed, roughly draining these and filling them firmly to within 2 inches of the rims with good soil, composed, if possible, of turfy loam two parts to one of decomposed manure; on this distribute about nine seeds, cover with about an inch of finer soil, water with warm water, and place in a heated pit. When the plants are well advanced thin out where necessary to about six plants, and support these with a circle of birch branches, such as can be had from a half-worn birch broom. Not much water will be required in the earlier stages of growth, though Beans should never be dry at the roots. By the time they are in bloom they will require much water, with liquid manure frequently, and always of the same temperature as the pit. If much crowded, in pits especially, the Beans are liable to damp off, and overcrowding, even if damping-off is prevented, invariably results in a light crop. From twelve to eighteen pots will yield several good dishes, and in most cases two or three small batches sown at fortnightly intervals are preferable to one or two larger sowings. A temperature ranging from 55° to 60° by night to 65° to 70° by day, with an increase by sun heat to 90°, with abundance of moisture to prevent attacks of red spider, will suit them admirably.

Potatoes in Pots (*Idem*).—An excellent cultivator who successfully grows early Potatoes in pots, says:—"Ten-inch pots are the best, a hundred of these will give many dishes of fine early Potatoes, and when properly managed there is no risk with them. A crop may be relied on at all times with no more trouble nor expense than was required with the beds and frames. A quantity of roughish loamy soil should be collected, and a little decayed manure mixed with it. Each pot must have a little rough drainage placed at the bottom, and afterwards be half filled with the prepared soil. This should be made level and firm, and the sets can then be placed on it. Two, three, or four sets may be placed in each, keeping them as far apart as possible, and afterwards covering to the depth of 2 inches or more with the soil. A cool house or frame protected from frost are suitable places for the pots at first, as with a little water the sets will soon produce growth above the soil; and the cooler and nearer the glass the plants are kept at this period the more robust will they remain, and this is a great point gained. Later on they are placed in early vineries or Peach houses, and there the tubers form plentifully and swell quickly. As the weather becomes warmer, about the end of March and beginning of April, they may be placed in frames with the lights over them. Where there is no room to grow many a few dishes may be had from one or two dozen pots, and when they are turned out we feel sure all will be satisfied with this easy and certain mode of securing early Potatoes.

Elaine Chrysanthemum (*W. Day*).—The flowers you have sent are very fresh and pure. They are, we presume, lateral blooms. Well-grown plants after the first flowers are cut break again and produce a second crop not less useful than the first, for if the blooms are smaller they are more numerous. The system of cutting plants in July appears likely to contribute materially to a desirable supply of Chrysanthemums during the early months of the year. Flowers for cutting, such as those before us, cannot fail being acceptable to those who possess them.

Pruning Climbing Roses (*A. D.*).—If the growths are very strong we should not shorten them so severely as you suggest. If they were taken from the wall and temporarily secured in a horizontal position, all, or nearly all, the back buds would break, and the shoots could then be secured vertically about a foot apart, and the wall would be well furnished; but if the shoots are not strong and vigorous they would be better shortened; or if they are closer together than indicated you might shorten the weaker and leave the stronger their full length or nearly so, merely removing the immature ends. In this way your wall would be furnished without lowering a limited number of strong shoots.

Conifers for Screen (*Idem*).—As we understand you to say "hardiness is the great desideratum," we cannot advise you to plant *Pinus insignis*, as a great number of specimens have been killed during severe winters. If you do not object to its dark colour *Pinus austriaca* is one of the most hardy and dense, but *P. Laricio*, the Corsican Pine, is preferable for positions near the sea. The desired height of the screen appears to us an important factor in determining what to plant. For screens or hedges 20 feet high there is no more suitable Conifer than *Thuja gigantea*, often called *Thuja Lobbi* in nurseries. It is close yet feathery, and retains its deep bright green hue during the winter, many others assuming a brown tint, which detracts from their cheerfulness.

Melons in Pots (*A Reader*).—Assuming a temperature of 70° at night, not falling below 65° in the morning, can be maintained in a house, Melons can be successfully grown in large pots without any bottom heat by persons who possess the requisite cultural skill. Obviously it would be of no use plunging the pots in a bed that is several degrees lower than the temperature indicated. Later in the season you will be able to increase the bottom heat, and you are more likely to succeed than by starting so early. You say your space for fermenting materials is limited, but do not mention the depth and width of the bed. It must be very limited indeed if you cannot supply the necessary heat by preparing the bed in April; and if you have very strong plants for planting then you may probably succeed better than by growing and fruiting them in pots. If you have had little or no experience in Melon culture, your safe course is not to commence so early in the season as this. We have grown excellent Melons by planting very strong plants in June without any bottom heat at all by artificial means, beyond applications of warm water, but we should have failed if we had attempted the work in February or March.

Training Melons and Cucumbers (*J. T. S.*).—There is no general length at which Melons are trained. Mr. Taylor allowed them to extend 20 feet or more at Longleat, training them longitudinally along the trellis. The usual practice is to train them across the trellis, allowing the leader to reach within a foot or a little more from the top, then pinching the growths that may follow. The trellis is then covered with fruit-bearing laterals, and only one or two leaves are permitted beyond each swelling fruit. The fruits of Cucumbers will need no extra support, provided the stems close to where the fruits are produced are secured to the wires.

Glazed Flower Pots (*Amateur*).—Your letter is clearly an advertisement, and as such can only be inserted in our advertising columns under the usual

scale of charges. Other firms make them than the one you recommend, and those who desire to extend their trade will no doubt do so in the ordinary manner. The writer of the article on page 101 confined himself to discussing the merits of glazed pots, and very properly did not attempt to obtain a cheap advertisement for any particular manufacturers; had he done so his remarks, if published, would have had little weight with discriminating readers.

Sempervivum tabulaforme (*Trike*).—If you pot the plants in rough turfy loam, with a fourth of dried cow dung and a portion of broken charcoal and a little sand, place them on the shelf of a warm greenhouse, water them judiciously yet sufficiently, they will make rapid progress. In the winter and early spring water must be sparingly given, but in the summer copiously. The plants also do well planted out in rich soil in a warm position in the garden from June to September. Cactuses and Epiphyllums are best raised from cuttings and by grafting. The address you request is Mr. H. M. Boller, Woodfield Nursery, Woodfield Road, Harrow Road, London, N. You will find some notes upon raising seeds of Cacti in another column.

Hard and Soft Putty (*C. L.*).—A little white lead mixed with putty will make it set hard in a few days; but gardeners never allow the use of that old kind of putty in these days, because once it gets dry they can hardly cut it when repairs or alterations are to be made afterwards. We have seen a good glazier break four squares of glass trying to mend one broken one, besides spending an hour and a half at the job, which a mere lad could do in five minutes, and without any breakage, if proper putty had been used in the first instance. Hothouse putty is made with whiting pounded down and sifted very fine, and boiled linseed oil, making it into dough as the bakers do their bread; the more the dough of putty is worked the better it will be, and it should be at least ten days old before it is used; in that time a large lump of it will "sweat"—that is, slightly ferment, which is necessary to give it the proper adhesive power. When this soft putty, as it is called, is allowed to dry thoroughly before it is painted over, it will last as long as the hardest white-lead putty, and at the end of twenty years be soft enough to be cut away with a knife. If, therefore, you wished to remove your greenhouse at any future time, you could easily take out the glass, pack it in boxes, and the timber-work could then be handled and packed without the risk or annoyance of breaking the glass.

Starting Dahlias (*F. J.*).—As you do not desire to increase the number of plants, but only wish to have them stronger, you had better let the roots remain dormant till the first week in April, then start them in pots in a very light greenhouse. As soon as growth is apparent the plants should be placed on a shelf close to the glass. They will then be very stout and short-jointed. You may either divide the roots or thin out the stems, selecting the best for forming the plants. They can be removed from the greenhouse to a frame early in May, and if well supplied with water will be in fine condition for planting after all danger of frost is over, and if placed in deep rich soil and copiously watered in dry weather, will attain to a great size during the season. If you start the plants anything like so early as your letter implies the growth will inevitably be weak and the plants unsatisfactory. It is only skilled propagators with suitable glass structures who are able to succeed in growing strong Dahlias by starting the roots in February and March.

Starting Tuberous Begonias for Bedding (*Idem*).—We fear you do not read the Journal so attentively as you ought, as we observe you often ask questions on a subject that has only recently been exhaustively treated. We cite from an article on this subject that appeared not long ago, and which is a complete answer to your question. A few of the secrets of success in preparing the plants and growing them successfully in beds—that is, if there are any "secrets" now-a-days, may perhaps be usefully divulged. These are the very essence of simplicity. Where persons fail is in over-preparing, over-nursing, or, to use a well-understood and expressive term, in coddling the plants in their early stages, then starving them afterwards. If we look at the plants and note their fleshy roots, succulent stems, expansive leaves, and large leathery flowers, it becomes apparent that they must have rich, free, generous soil, and abundance of water—that is, when they are in full growth. It is also clear that all plants of this nature from Balsams to Begonias are peculiarly liable to be drawn by excessive heat and insufficient light in their early stages. If anyone wants to see how stout and sturdy Balsams can be grown let him sow some seed in pots in May, and plunge these pots in a heap of fermenting materials in the open air. If he wants stout Begonias for bedding let him start the plants on similar principles of affording them gentle bottom heat, but not starting them so soon that they cannot have abundance of light and air to keep them dwarf and sturdy. The precise time of starting can only be determined by means of growing the plants afterwards, but, as a rule, early in April would be safe for the majority of cultivators. When once started the plants must be kept steadily growing. There must be no check, and as a rule they are far better if they are never potted. If Begonias are potted, as they often are, grown nearly a foot high under glass, then placed in a frame to "harden," their pots at the same time crowded firmly with roots, and eventually planted out, they will not flourish. Their owners wonder why they do not start and grow freely, concluding the plants are "not fit for bedding." It would be a wonder if plants thus "prepared" did thrive. Even Calceolarias will not do so, as most persons have found out, and they adopt a simpler and more rational mode of preparation. In order to succeed with Begonias we must go back to simplicities. Start the tubers in boxes, then if the plants when an inch or two high can be planted 4 or 5 inches apart in good soil on a gentle hotbed in a pit, or over which a frame can be placed, there to remain till planted in the beds, there can be no better preparation. Failing this they may be grown thinly in boxes, the compost being light and gritty, resting on a layer of decayed manure. Of this the roots will take possession, and in due time the plants can be quickly yet carefully planted in the beds with roots uninjured, stout, healthy, hungry, and ready to immediately extend into the soil in which they are placed. A root-bound plant cannot do this. It tries to do so, and a few fibres start from the wire-like roots here and there that are curled round the soil, but the growth is never free, and the plant struggles for existence. It may not die all at once, but it cannot make free progress, and then "Begonias are no use for bedding." Better would it be to plant the corms in the beds on the 1st of May and leave them to take their chance, than to prepare them in this root-bound irrational fashion that more than

anything else has brought Begonias into disrepute as plants for the flower garden.

Names of Fruit (*Merse of Berwickshire*).—1, Golden Winter Pearmain, commonly called King of the Pippins; 2, Grey Leadington (?); 3, Downton Nonpareil. (*Colonel Gleig*).—1, Golden Pearmain; 2, Golden Reinette; 3, Eldon Pippin; 4, Golden Noble. (*F. J.*).—Reinette de Canada. (*F. G.*).—The Pear is not known.

Names of Plants.—Several correspondents have sent us Camellia flowers for naming. These being varieties and not species we do not, as we have many times stated, undertake to name them. There are so many forms so closely resembling each other that they cannot be satisfactorily identified except by comparison with others in a large collection. The same rule applies to all varieties of florists' flowers. We do not refuse to give the name of a Camellia that we can determine with accuracy; but in a case of doubt it would be inadvisable to give a name that might not be correct. (*E. P.*).—*Clematis indivisa lobata*.

Feeding Bees (*Old Subscriber*).—Your bees are probably starving. Give them syrup in shallow vessels, which you can easily place under the hive.

COVENT GARDEN MARKET.—FEBRUARY 13TH.

TRADE continues quiet, Grapes scarcely maintaining their value. Cucumbers lower. Kent Cobs stagnant.

GRASS SEEDS FOR PERMANENT PASTURE.

THE subject of "Laying down Land to Permanent Pasture" was discussed in this Journal on the 5th, 12th, and 19th of February, 1880. Since that time, however, a great revolution has occurred, or a great necessity for changing our opinions upon the subject of seeds to be used for the purposes. Much care has been bestowed upon the subject, which has been considered in a thoroughly practical light by an excellent authority, who has given us the full benefit of his experience—we allude to Mr. C. De Laune Faunce-De Laune, whose essay appears in the Journal of the Royal Agricultural Society of England for 1882 "On Laying down Land to Permanent Grass," and which will be of immense importance to the owners and occupiers of land, and more particularly at this period of depression in agriculture, when the statistics show that a large increase of land laid into pasture has taken place during several years past. No doubt in the future obtaining seeds for the purpose will be more simple, better defined, and at some considerable less cost than in the past. It is notorious that a great want of knowledge has existed upon the subject, which has been shown not only by the farmers, but also in some cases by the seedsmen, as regards the habit of growth and feeding properties of grasses produced by seeds commonly used for the seeding of land for permanent grass, in consequence of which a large number of seeds of sorts ill adapted for the purpose have been included in the mixtures. Still we cannot but admire the interest taken in the subject by those firms and seedsmen who have taken great pains in directing the farmers as to the value of the seeds which, in their estimation, both as to sorts and quantities, were best adapted for use on the different soils and climates of the various

counties and districts of England, Ireland, and Scotland. Much trade has been done in selling grass for use in our colonies, as well as the continental States; and no doubt as the cultivation of land in America, Canada, &c., extends, that a great future for the seedsmen will open abroad for them; but more particularly shall we expect this after the full experience of those who have studied the matter of selection of seeds has been more fully developed and admitted as correct in practice.

In the essay above named the author says—"Although I have, during the last nine years, bestowed much attention on the formation of permanent pastures, I should have hesitated to undertake the task of attempting to enlighten others, had I not been assured by many very competent advisers that a promulgation of the results of my experiments would be greatly for the public advantage; the more so, as on many essential points my views differ materially from those of most writers on the same subject. In the limited space of this article I intend to confine myself to that which I deem the most important—viz, the kinds of seed suitable to be laid down. Unfortunately for owners and occupiers of land the grossest ignorance prevails about grasses. To many landowners and farmers almost every herb that is green is considered to be grass; hence the ordinary circumspection used in purchasing grain-crop seeds has not been exercised in the case of grass seeds. It is generally, I might almost say invariably, alleged, and truly so, that newly formed pastures have been found to deteriorate greatly after the first two or three years. I will explain my view of the reason of this determination and point out the remedy, and in so doing correct what I conceive to be some erroneous impressions that are generally entertained respecting grasses. The terms 'coarser grasses,' and 'finer grasses,' which are so frequently used, have led to serious mischief in the formation of new pastures. The coarser are popularly believed to be the inferior, and the finer grasses the better sort, but in reality the four best grasses for pasture are all large grasses, and come, popularly speaking, under the head of coarse grasses. There are perennial, biennial, and annual grasses. The two latter ought, in my opinion, under all circumstances, to be carefully excluded when a permanent pasture is desired. The use of short-lived grasses and of biennial Clovers, coupled with an insufficiency of proper seed, is the main cause of deterioration of new pastures after the first two or three years.

"The four coarse grasses valuable beyond all others for permanent pasture are Cocksfoot (*Dactylis glomerata*), Meadow Fescue (*Festuca pratensis*), and its ally, Tall Fescue (*Festuca elatior*), Catstail or Timothy (*Phleum pratense*), and Meadow Foxtail (*Alopecurus pratensis*). These five grasses should form the bulk of all pastures on good soil, either for sheep or cattle. The finer or minor grasses are Crested Dogtail (*Cynosurus cristatus*), Hard Fescue (*Festuca duriuscula*), Rough Meadow Grass (*Poa trivialis*), Fiorin (*Agrostis stolcnifera*), Sheep's Fescue (*Festuca ovina*), and Golden Oat Grass (*Avena flavescens*). A meadow composed of the above would be perfect as regards grasses, assuming that the proper proportions are used; it would produce food for stock during nearly every month of the year. The Clovers which should, however, be used in a much smaller proportion than the grasses are permanent Red Clover, Cow Grass, Alsike, and White or Dutch Clover. Seeds of Milfoil or Yarrow (*Achillea millefolium*), ought never to be omitted. The above are really all the plants required for a permanent pasture of the finest quality on first-rate or medium soils throughout Britain. On inferior soils or soils possessing special qualities some of these grasses would not be suitable, and a selection must be made. Thus, on dry lands, Foxtail, Rough Meadow Grass, and Fiorin should be omitted, and a smaller quantity of Meadow Fescue used, while a greater proportion of Cocksfoot, Crested Dogtail, and Yarrow should be substituted."

This lengthened quotation has been given because it exactly describes the new movement or changes required in the seeding of land for permanent grass. When compared with the mixtures heretofore recommended by most writers on the subject, and the major portion of the seedsmen who furnish ready mixed grass seeds for the purpose, and which have previously been accepted by the farmers, who in general through not studying the matter for themselves and their interests, have trusted to seedsmen to prepare mixtures for them. We were somewhat in the same position as most farmers, for during eight or ten years we had trusted to firms to supply grasses of our choosing, but we are still in the dark whilst making our own selections; for although we objected to inferior sorts of grasses, yet we were induced to use seeds such as Italian Rye Grass, Perennial Rye Grass, and other varieties of Rye Grass. Now, however, we can see the mistake that was made. Rye Grasses make a great show, and although cheap were the principal cause of all the subsequent failures of the plant so common in the previous system of seeding.

About four or five years ago we recommended a friend to sow a mixture of Rye Grasses with the best permanent grasses, but when we viewed the land a few months ago our friend complained that all the grasses, except Cocksfoot and some Dutch Clover, had entirely dis-

appeared, and in that state we found it, for the Coeksfoot Grass left was not thick enough to furnish a good turf, although some Dutch Clover still remained ; yet the food for dairy cows had been abundant throughout the year. Immediately we saw the field we felt how correct the experiments and recommendation of Mr. Faunee De Laune had been, and that they were sound and safe to be acted upon, because all other grasses which had been sown had failed in contributing to permanency of the pasture, although they had yielded a fair produce for the first two years. The mistake has occurred in this way, for the farmers were informed that the varieties of Rye Grass were necessary to furnish the bulk of the produce for the first two or three years, during which time the permanent varieties would be gaining strength, and eventually outgrow everything else, and form a thick pasture of the best kind. But we can now see how, with others, we have been misled ; for although some sorts of grasses were much cheaper per pound than the best varieties of permanent grasses, yet it is clear that farmers almost to a man were, until Mr. Faunee De Laune opened their eyes upon the subject, completely deceived. The seedsmen supplied such seeds as the farmers were satisfied with, and thus the fallacy became popular without disadvantage to the seedsmen until recent events occurred.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—This will continue so as long as the weather is so stormy and changeable, but we have never known a finer time for sowing late Wheat than has prevailed since Christmas, for although the weather until the last week in January was mild and foggy without much rain, it was very suitable for Wheat-sowing in all cases where the land was ploughed and sown simultaneously. When the seed can be properly buried or covered by the action of the harrows the land cannot be considered too heavy ; for in the succeeding months, if the weather proves either frosty or ever so dry, the Wheat plant will always do well when the soil is heavy and close without being drenched by heavy rains at the seed time. Spring Beans, too, may have, and no doubt have been drilled on some soils during the month of January. Even now while we write (Feb. 4th) we notice fields of London clay, and the land ploughed in small ridges for Wheat, such as the late Mr. Mechi used to call it, "dressed in corduroy." Although we have had heavy rains, yet the intervals of strong drying winds have prevented water showing in the land furrows where finished-off in a husband-like manner, and in nearly every instance the Wheat plant is regular, whether sown in October, November, or December ; in fact, much that was sown in October, it is said, looks too strong, but to our mind that will only be proved by the spring and the summer, for if we have an early harvest the Wheat will do well and go on without any serious check. Chalk-carting will still be going on, also carting manure from the towns where farms are near. We know in some cases where the moss litter is used for cab, omnibus, or tramcar horses, the manure is removed by contract, the farmers giving so much per ton or load. Now this manure is very valuable, for the moss-litter manure is composed of humus saturated with urine and mixed with the excrement, making combined a first-class manure for light soils, either as arable or pasture. How many farmers having peat on their farms may go and do likewise ! But do they ? It is too true that they do not provide peat in a dried state for this, although they may do it so easily in many cases with great advantage, it is lost sight of. This is especially important in pasture districts where straw is always scarce, but peat is more or less available as a substitute. Carting earth to store heap, also taking off earth at the sides of local or farm roads, may now be done, and such earth is very valuable for the making of compost, seeing that its accumulation has been drift from the roads. If we should obtain frost enough to bear the horses and carts without tracking, the various compost manures may be laid out on pasture or park lands without injury.

Hand Labour.—In the enclosed woodland districts men will now be employed in cutting and converting underwood into bundles for various purposes, such as hoops, hop poles, and sparwood. In fact, planting is worth the attention of the home farmer, for we find in various instances much poor land has fallen into hand upon some estates, which although cultivated when rents were high and prices of produce fair and reasonable, is now in these times of agricultural depression such land pays best and proves most beneficial when planted with Larch Fir as thick as Cabbages, where they can be sold well as hop poles at the age of about twelve years. If no demand exists for hop poles, ordinary underwood of the best varieties may be planted for conversion as above named. If not, some soils unproductive in their waste, although not of sufficient value for corn-production, may be laid into grass in accordance with the plans and system of seeding which our columns for several weeks to come will bring into prominent notice for the benefit of the home farmer and others whom it may concern. The weather when open and mild, as it has been for some time past, will not interrupt the forking-out of couch grass upon all dry and friable soils where the roots are now growing, such as Swedish Turnips, Kale, &c., and which crops ought, as well as land intended for Potatoes, be looked over, the former before feeding with sheep, the latter before ploughing and planting.

Live Stock.—Fattening sheep will now require a liberal allowance of dry food to counteract the effect of the roots, which, owing to the mildness of the season, have not only lost a portion of their feeding value by

early sprouting, but contain also an unusual proportion of moisture ; in fact, it is a question what food should be used for the purpose of correcting the state of the root crops. We do not approve of cake for that purpose, but rather the use of Beans, Barley, or damp and inferior Wheat crushed and in admixture, not only for the purpose of checking any ill effects from undue moisture, &c., but also because, if we use the produce of the farm, which is now selling so low in price, it may contribute to the advantage of the farmer in two ways. First, beneficial action in fattening his sheep, and also by withdrawing a considerable portion of the grain supplies from oversupplied grain markets. For young store cattle and dairy cows the open weather has been extremely favourable, as they have been wintered in the pasture districts with more economy than usual. In various provincial towns lying in pasture districts it is matter for remark that sound and sweet fresh butter is not to be obtained in quantity proportionate to the demand. Let the dairy farmers, but particularly those who have little or no arable land attached to their farms, make arrangements so as to have one-half or one-third of their cows to calve in the month of October and November, and feed them during the winter upon ensilage, the produce of their own pastures, instead of hay. In this way the supply of butter may be made equal to the demand, at a high price sufficient to make it beneficial to change the old system.

OUR LETTER BOX.

Channel Island Cattle (V. C.).—These are never too old for milk-selling and butter-making if they will bring a calf every year, and continue in good health. They are never too old if they are good and large milkers, nor is it any use to attempt to say how long they should be kept, especially if for pets in suburban districts, because when they are aged they cannot be fattened to any profit, but whilst they yield a full quantity of milk retain them by all means. They will sometimes milk profitably until fifteen years old or more. A mild climate suits them best, but we never knew one die from old age if free from disease.

Alderney Cow (T. S.).—We do not think it advisable to keep a heifer which is a hard milker. It will be best to sell her for what she will fetch at the time she springs and shows for calving.

Management of Cows (C.).—To keep cows in health up to the time of calving they should have proper exercise and not be allowed to go dry, but be milked until they spring for calving again. They will then continue healthy, and not lay on internal fat, which is the cause of nearly all the disorders to which they are subject at the time of calving, and it applies with greater force to Shorthorns and the Suffolk Polls. Channel Island cows are not so liable to the drop or puerperal fever at calving time. It is better for cows to live on grass only or ensilage for two months before calving ; but in case of being fed with roots and hay, a very moderate allowance is necessary, certainly not so much as they can eat, but with access to water at all times. At the time of calving the cows should be milked quite dry twice a day. After the calf is born the cow should have a warm bran mash ; it is, however, an open question, for some successful dairymen never give anything but water, or cold bran mash after calving. Cows should be kept very short of food several days before calving, and always have access to rock salt. With regard to the rearing of the calf, if it is for stock it should have a drink of new milk, if it is not allowed to suck the cow. Sometimes they are weaned at birth ; they are, however, generally allowed to clear out the udder after the principal part of the milk has been drawn away for a week or ten days. Afterwards they are weaned and allowed new milk for a month, and then skim milk with a little cake or bean meal mixed until they begin to eat. They may then run out into a dry paddock at daytime, but still get a little milk and meal twice a day until they obtain grass enough to keep them in condition, but they should go into pens for warmth during the night. If calves are reared for veal they may suck the cow, and have beanmeal balls given when they require it. If the calves are required to be fed on for fat animals or for show purposes, they will suck the cow for five or six months, and then be fed separately upon the best of everything—good roots, hay, cake, and meal.

REMARKS.

3rd.—White frost early, then fine, but cloudy in afternoon.

4th.—Fine, but not very bright.

5th.—Dull and overcast.

6th.—Dull morning ; fine afternoon ; moonlight evening.

7th.—Dull, but fine and bright in afternoon.

8th.—Cloudy all day, with fog from 11 till 3 ; sprinkle of rain in evening.

9th.—Overcast nearly all day, with occasional rain and some wind.

Rather cooler than the previous few weeks, but still above the average.—G. J. SYMONS.

FORCING VINES IN POTS AND PLANTED OUT.

IN producing Grapes as early in the season as possible the majority of persons are anxious to spare permanent Vines such a strain upon their energies as they undergo in forcing, and for this purpose Vines grown and prepared in 10-inch pots are forced for yielding early Grapes. Never, I think, in the whole history of horticulture were so many employed for this purpose as at the present time. Certainly some consider that the produce from such Vines is not of much account, and only useful to maintain a continuous supply. It is scarcely to be expected that the fruit should be quite equal to that from those started two, or even one month later in the season, yet some wonderfully good fruit can be produced from Vines in pots. Up to the present time, however, I have failed to obtain from Vines confined in the pots in which they were grown fruit equal in size of berry and quality to that from others that have been transferred into pots 2 or 4 inches larger. The latter is preferable, and I am more convinced than ever that the little extra labour occasioned by the potting is more than repaid by the better quality of the fruit. Only last year I had the pleasure of seeing a house of Vines in pots grown on the principle I described in these pages a few years ago, which for finish, size of berry and bunch were superior to any I had before seen. If the fruit had been the produce of permanent Vines it could not have been expected better; in fact, a house full of such fruit early in the season would have been regarded as a grand success.

It is not my intention to detail the system again, and only allude to it because the time of year has arrived when it can be carried into operation. Those who attempt the re-potting must be careful how the watering is performed until the roots are growing freely and have taken full possession of the new soil. If the old ball is allowed to become dust dry only poor progress afterwards need be anticipated; indeed experience proves that growing Vines annually and fruiting them in the pots in which they are grown is by no means the easiest or most economical system. Transferring the Vines when the roots commence action into larger pots is preferable, but even this is not so good as planting out the Vines. Some may urge that good Vines can be purchased at moderate prices, and that the supply of fruit will than compensate for the first outlay. This I do not deny, and have followed the practice myself when for the want of room I have been prevented growing those raised at home.

The best supply of early Grapes can be obtained by planting out well-grown Vines in a small house in narrow borders purposely prepared, not to be destroyed after one crop, but to be retained for a number of years. Those who have Vines in pots now commencing growth and showing their bunches have them in the most suitable condition for this purpose. The borders need not be more than 18 inches wide, and the same, or even less, in depth. Suppose the

house in which they are to be planted is a span-roofed structure, with a bed 3 feet wide on each side and the walk down the centre. If the borders are half the width of the beds, and the depth is in accordance with the width, it will be ample for the Vines for at least four years. The borders may be composed of good loam, a little wood ashes, quarter and half-inch bones, and a little fresh lime sprinkled amongst the soil as the border is being made. If the loam is heavy, charcoal, broken bricks, or even coarse sand may with advantage be used; if, on the other hand, it is light, reduce clay to powder by drying and add it to the soil. The borders should be well drained, so that the soil employed cannot become saturated and sour about the roots.

In such a structure the Vines should be planted on each side about 2 feet apart, allowing every alternate Vine to extend to the eaves of the house on the opposite side. This arrangement will leave the Vines on each side after the first crop has been gathered 4 feet apart, while the rods when they have extended their full length will be 2 feet from each other. Before planting, be careful that the soil of the borders has become sufficiently warm, so that the roots will not be checked. The old balls of soil and roots must be in a moist condition before they are placed in the border, and it will be wise to make three or four holes through the ball before planting to insure water entering afterwards. If they are once allowed to become dry it is difficult to get them thoroughly soaked after, and much injury, or even the loss of the crop, may be the result. The soil of the border should be pressed firmly round the roots in planting, and when finished the surface should gradually slope inward to the stem, and be allowed to remain in this condition until the roots are growing freely in the surrounding soil.

It not unfrequently happens that in forcing a number of Vines in pots, however well they may have been grown, a certain per-centage may fail to show fruit satisfactorily. These should not be thrown away, unless the cultivator has sufficient for planting without them, but accorded positions where they can extend for fruiting the second year. It will be understood that the first crop is to be taken from every alternate Vine, and after it has been gathered the rods can be cut out to give the others every chance of properly developing and maturing their wood. It is not necessary to remove the whole of the fruit from those intended to bear the second year, unless the temporary Vines are capable of carrying an ample supply. I have taken six bunches from the Vines the first season they were planted, on an average 10 lbs. of fruit, and they have done well the following season, but it is unwise to crop them so heavily.

After the Vines are planted, if they have not broken strongly at the base—and they seldom do so early in the season—peg down upon the border the rods intended for the second year—that is, the bare portion; the remainder may be taken upright and tied to the wires. By this means the canes will throw out abundance of fresh roots, which will not only add to their strength and vigour the first season, but be a great help to them in the second. A small house was planted with Vines after fruiting one year in 14-inch pots early in the year 1882; these were pegged down early last year, and have made abundance of roots, in fact sufficient to be independent of their former feeders. They have carried three good crops of fruit, one in large pots, two since they were planted out, are again this year showing fruit well, and have increased much in strength since they were pegged down.

I am convinced that Vines planted out in the manner detailed and liberally treated will give a greater yield of superior produce than it is possible to grow under the system generally practised at the present time. From the appearance of the Vines upon which my experience is founded I believe they will bear creditable crops of fruit for at least half a dozen years. Overcropping must not be tolerated. I am no advocate for fourteen or fifteen bunches of inferior fruit, and consider six well-finished bunches ample; in fact,

it is a heavy crop when they swell to an average 10 lbs. of fruit.

If the Vines are strong at the end of the fourth year the remaining portion of the border should be made. If any show signs of weakness give them a year's freedom from the strain of fruit-bearing and encourage a young cane from near the base. When planted thickly as advised, after they have fruited for a number of years a young cane may be encouraged from the base of every alternate Vine, removing the lower spurs to give it light. After it has been grown one year remove the old Vine, and then allow the young cane to grow the following year without bearing fruit, so as to become thoroughly recruited. By this means the life of the plants is renewed, and in consequence extra vigour and fruitfulness is the result.—WM. BARDNEY.

NOTES FROM THE NORTH.

— *CYPRIPEDIUM SPICERIANUM*.—Probably the flowers of this lovely Lady's Slipper last longer in perfection than those of any other. There is a plant in bloom here that expanded its flowers the first week of November, and there is as yet (February 16th) not the slightest indications of its fading. The house in which it stands has been kept at 60° at night, with an amount of moisture sufficient for *Vandas* and similar Orchids. The stock of plants from which the blooms were cut as they opened were removed a month since into a house where, from great command of pipes, the night temperature is easily kept at 70° with a very moist atmosphere, and the effect has been magical in the expansion of leafage and deepening of their green. Evidently it is a plant that grows most vigorously in a high temperature and saturated air.

VANDA SANDERIANA.—Two plants of this grand *Vanda* stood in our *Vanda* house all winter without showing signs of making fresh roots. It, too, was placed in the warmer and moister house along with *C. Spicerianum*, and it commenced to make roots almost directly. From the appearance of this *Vanda* I suspect it requires more heat than the tricolors or *suavis*. A writer has recently said that it resembles *V. cærulea* in its growth, but I fail to see anything like a resemblance in two plants of it here to some eight or nine plants of *V. cærulea* growing in the *Cattleya* house; but perhaps there may be varieties of it, like all other *Vandas*.

CALANTHE VEITCHII.—It is affirmed by some that there is only one variety of *Calanthe Veitchii*, and that the variety of colour is merely the effect of exposure to different degrees of light. I, however, have grown the two varieties year after year side by side under precisely the same conditions, and have always found them quite fixed in their shades of colour as well as in the shape of their bulbs, and maintain that the one with the contracted middle part of the bulb is not worth growing as compared to the other.

DENDROBIUM HILLII.—This distinct *Dendrobe* is well worthy of more attention than it receives, and few Orchids are more ornamental when well flowered. I have to-day (February 16th) cut two spikes of it from one growth or stem, the flowering portions of which without the stalks measured 20 inches long. The same plant has several other spikes on it. It is considered a shy flowerer, but if grown in a cool airy house, and after it has made its growths it be kept dry for three or four months, it flowers freely enough. Our plant has not been shifted for eight or ten years, and the pot seems to be full of roots and nothing else.

MATERIAL FOR POTTING ORCHIDS.—Having passed a very considerable number of Orchids through my hands in the operation of potting during the last two months, I have noticed two things in particular—namely, that where epiphytes are found growing in sphagnum and crocks with next to no peat inter-mixed, the roots and growths were always in better condition than where the latter ingredient was more abundantly used. It would be difficult to understand how peat can get up a tree, though that does not by any means prove that an Orchid in the cleft of a tree does not get manured, but it must be directly from the surface. And it was also found that where such plants as *Odontoglossums* and *Cattleyas* have had a larger surface, but very little depth of material to grow in, they were in much better order than where the surface was less and the depth greater, an inference which might also be drawn from the condition of such plants growing on trees. By the way, a celebrated writer not very long since declared he saw lumps of

loam sticking to newly imported masses of *Odontoglossum Alexandræ*. It would be interesting to know how the loam got up the trees. In potting *Cattleyas* it was also found that where the crocks were placed edgeways the roots had a far more vigorous hold of them than when put into the pots less regardless of their position. In clearing the old material from the roots a most effectual way is, after removing it all from the surface, to give the pot a few sudden plunges in a barrel of tepid water. This forces every particle of decayed material out at the surface and at the holes in bottom of pots, which operation is also most effectually carried out when the drainage is all carefully arranged edgeways, and where a plant has been found with its roots so welded to the inside of the pot that in many cases they must be very much injured if an attempt were made to liberate them even by breaking the pots, they have been placed entire inside a larger pot when a shift into a larger was considered desirable. In this way the roots are not injured, and fresh-made ones find their way from the top into the larger pots.

MILDNESS OF THE WEATHER.—This may be judged of when it is said that on Friday, February 2nd, all our large-foliage plants were taken out of the stoves into the yard and thoroughly drenched with petroleum and water to make sure that no insects were left on them as a preparatory operation to their being shifted into larger pots when that was necessary. Speaking of petroleum, it is the cheapest and most effectual of the many insecticides of which we have had experience, and the destruction of mealy bug was despaired of till we employed petroleum. The enemy was so general that it was found in legions on the under sides of the iron gratings that form the paths of the houses; but paraffin soon solved the problem, and I do not believe there is a bug in the place, nor has there been a plant injured by the oil.—D. THOMSON, *Drumlanrig*.

SPRING TREATMENT OF STRAWBERRY PLANTATIONS.

THE best of all ways of growing Strawberries is in rows, which may be from 1 foot to 2 feet apart, according to the variety. Some who only try to secure large fruits grow the plants singly, 3 feet apart every way, but in my opinion this is not the most profitable method. The best and most fruitful Strawberry plantation I have had was one where the rows were 3 feet apart—that is, from centre to centre of the rows, but each row was in reality 18 inches wide, and a bare space of the same extent was left between them. The plants in these strips were grown in a mass together, and as they have been in existence for ten years they have, through adding top-dressings, become higher than the ground between, and this is a great advantage both in keeping the blooms and fruits clean, and the crowns are well exposed to the action of the sun and atmosphere, which is an important point.

Some growers, whose whole attention to their Strawberry plantation consists in gathering the fruit, allow what may at one time have been rows to become a mass of runners, and every inch of the surface of the soil is covered, but when this happens the plants will soon degenerate and fail to produce fruit of any reasonable size or in profitable quantity. It is this system of neglect I wish to speak against, and now is the time to remedy such evils. The first fine day should be taken advantage of to line off the original rows. Remove all superfluous plants, and leave the ground between the rows perfectly clean. In digging up the plants the whole of the soil need not be upset, but cutting them off like turf is the best way of clearing them, and to dispose of them finally they should be burned. All weeds should be taken up, and a sprinkling of short manure then placed amongst the plants. At the same time a good coating of manure should be applied to the cleansed ground, and this should be forked-in. As soon as the plants commence growing they will at once reap the benefit of this treatment, and by the time the fruits are swelling the cultivator will be well repaid for his labour.

I always have all superfluous runners cleared from our plantations in the autumn, but some may not have the opportunity then, only the operation should not be delayed after this time, and the sooner the manure is applied the better. Putting straw or dried grass around the plants at fruiting time to keep the fruit clean is very well, but this will neither increase the size nor number of the fruits. To do this manure is required liberally in poor soils, and that the plants may benefit fully by this they should have it to feed on from the time growth begins. Where the roots are plentiful near the surface it is not right to disturb and break them, and only a top-dressing should be given, but in the centres of the vacant spaces between the rows a good quantity may be forked into the soil, as the roots will find their way to it before long. Plantations which have only been

formed in good soil last year, or not long ago, should not require any feeding yet, but all plants of over two or three years old are benefited by a rich top-dressing in spring.—A KITCHEN GARDENER.

GLAZED FLOWER POTS.

TWENTY years back I grew Pelargoniums, Primulas, Cinerarias, &c., with very great success in glazed pans. The Pelargoniums took first prizes wherever exhibited, and the late Mr. Fleming used to make great comment upon them. I have at the present time in glazed pans (ornamental) from Matthews, Royal Pottery, Lycopods and Ferns that have been twelve months in them quite fresh, and used for room-decoration without any renewing.—BLACK PRINCE.

AFTER reading Mr. D. Thomson's interesting article on the above subject (page 101) it struck me that as many plant-growers are not in a position to get glazed pots, a coat or two of paint on the ordinary flower pot would answer the same purpose, and the cost would be but trifling, as the painting could be done in almost the same time that it takes to scrub a dirty pot. We paint tubs in which we grow plants, and no bad results follow. One of the finest specimen Heaths I ever saw was grown for many years by the late Mr. Dickson at Ferguslie House, Paisley, in a painted wooden tub; so that I think there need be no fear of plants not thriving in painted earthenware pots.—H. HENDERSON, *The Gardens, Woodbridge Park, Guildford.*

VEGETABLES FOR WINTER SALADS.

THE culture of vegetables for salad purposes is by no means one of the least important of the duties devolving upon the gardener. Most cultivators are required to furnish a supply of salading during autumn, winter, and early spring; in some instances a constant supply in quantity and variety. Simple as this task may appear to those who have not hitherto been called upon to do so, it is not an easy one, requiring as it does the exercise of considerable skill and forethought in accomplishing the object. A good salad ranks next in order to dessert, and in many establishments the former is required to consist of vegetables of first-rate quality.

Having to maintain a daily supply for my employer's table I will give your readers the benefit of my experience. First let us see what vegetables are required, and as seed lists are now to hand we should procure seeds of the following—Corn Salad (Italian) or Lamb's Lettuce; Purslane, green and golden; Chicory (Witloof); Dandelion; Lettuce, All the Year Round, Hardy Hammersmith, and Brown Cos; Endive, Moss Curled and Improved Batavian; Radishes, Turnip and Long-rooted; Mustard, white; Cress, common and American, and I need scarcely add Celery and Beet. I will now proceed to describe their several methods of culture and after management.

CORN SALAD (ITALIAN) OR LAMB'S LETTUCE.—Seeds of this should be sown about the end of July on a border for affording produce in September, and continued at intervals, according to the demand for it, until the end of October. Keep the soil moist, or the seed will not germinate satisfactorily. As soon as the young plants have formed their rough leaves they are fit for use; but should only one sowing be made and it is desired to have a moderate supply, then thin out for present use the smallest, leaving the strongest to form large branching plants for a later supply. When frost sets in these should be covered with spare lights, or, if these are not available, with dry litter or mats. Take care, however, if protected with the latter not to cover longer than is absolutely necessary, as the flavour is thereby impaired. By frequent sowings, as above recommended, a supply of this can be secured until May.

PURLANE.—There are two varieties of this, the green and the golden, seeds of which should be sown early in August. Successional sowings may also be made according to the demand. Purslane requires a copious supply of water, lacking which it becomes too tough for salads. It may, however, be used for cooking and serving up in the same manner as Spinach. It is ready for salads as soon as it is 3 inches high. An outdoor supply cannot be depended upon after October, therefore should any be required afterwards it is safest to sow a pinch either in a frame or in a box and placed under protection.

DANDELION.—This is perhaps one of the easiest plants to cultivate, and one of the most troublesome pests when once it gets a firm hold in the garden. Seeds may be sown in spring in a spare corner of the garden, and in October the roots can be lifted and stored away for use till wanted. I commence forcing this in November, when roots are placed in any ordinary soil in a large deep box with a lid attached and perfectly dark. This box is placed under the stage of the forcing house, and in a couple of weeks the beautifully blanched and crisp leaves are

ready for cutting. It is highly esteemed by my employers on account of the brisk agreeable flavour it imparts to the contents of the salad bowl. If sufficient roots are forthcoming, by introducing batches into heat at intervals a supply can be kept up for a long time.

CHICORY.—One of the most valuable salad plants we possess for winter use, especially the variety known as Witloof, a more delicious and palatable form than the other varieties of Chicory. To have large crisp crowns, attention must be paid to the cultivation of the roots when growing. The soil should be well trenched and manured, after which seeds should be sown in April in drills a foot asunder, thinning out the young plants when large enough to handle to 9 inches apart in the row. Assist during their period of growth with occasional supplies of liquid or artificial manure. Lift the roots in October, and store away among sand in a cool shed until required for forcing. The roots may be forced in boxes similarly to the method recommended for Dandelion, or by putting a number of roots in a large pot and then placing an inverted flower pot over the crowns to exclude light, and standing it in a heated Mushroom or other warm house as most convenient. We, however, prefer the use of boxes as above recommended, as a much larger quantity of roots can be placed therein at one time.

LETTUCE.—As nearly every gardener can grow good Lettuces I shall not take up space by full details of its culture. To have a good supply during winter requires a little forethought in making the sowings and growing strong plants ready for taking up and storing in frames on the approach of frost. Much, too, depends upon the varieties grown for that purpose. Some, although good summer varieties, fail to answer satisfactorily for winter work. We have tried many varieties this last season, and find that there are no better Cabbage Lettuces than All the Year Round and Hardy Hammersmith for ending the winter. The best Cos we find to be the Brown-seeded Bath. I sow the last week in July for the winter crop. As soon as the plants are large enough to handle they are pricked out on Celery ridges and watered carefully. When the plants are established, weekly supplies of soot water are given them to encourage free growth. On the approach of frost they are lifted and stored in cold frames, which are well ventilated in cold weather.

Thus far I have written of large plants; but when a month or so has advanced in the new year a change is sought for, and as a rule the old plants are not appreciated, having become somewhat tough and deficient in flavour. How, then, is the difficulty to be overcome? I reply, By sowing a few pinches of surplus seed from last season; or, better still, the seed saved from a few plants allowed to seed in the summer. I take advantage of an inside border of an old Muscat house, and sow plots of three square yards at a time. This house is started early in the new year, when the border is slightly pricked over with a fork and manured with old hotbed refuse. In a few weeks after the seed is sown the young plants are 3 inches high, and are then fit for use. These are drawn up in little bunches, and are sent in with Mustard and Cress to form a salad. I grew a plot of Sutton's Earliest Brown Forcing Lettuce last season in this manner, and my experience of it as a tender Lettuce for such a purpose has led me to grow more of it this spring. Sowings may be made at intervals until the season has sufficiently advanced to do so out of doors.

RADISHES.—The varieties best adapted for early use are the Early White and Red Forcing Turnip-rooted, French Breakfast Olive-shaped, and Wood's Early Frame Long-rooted. A slight hotbed should be made with a few leaves and dung, the surface of the latter being covered with several inches of light rich soil, and as soon as the soil has become warm sow the seeds, afterwards slightly covering with soil and watering with tepid water. Should cold weather intervene it may be found necessary to apply a lining of hot dung around the frame to support the temperature. If allowed to suffer from an insufficient supply of water the Radishes will become hot and tough and unfit for a good salad.

MUSTARD AND CRESS.—These are indispensable constituents of the winter salad bowl, and besides possess the merit of being easily grown. As Cress, however, takes nearly double the time in germinating that Mustard does, only one sowing of the former need be made to a couple of the latter. Seed sown in shallow boxes in a gentle heat at intervals according to the quantity in request will secure an ample and constant supply.

ENDIVE.—This is one of the best of salad vegetables for autumn use. It supplies an agreeable change to the salad after the Lettuce, &c., of the summer months. In some establishments it is grown on a large scale, both for private consumption and for market. Some extraordinarily fine examples are to be oftentimes

seen in Covent Garden Market, thus showing the great perfection to which the London market gardeners grow this. Still we are told we are far behind our French neighbours in the high-class productions of salad vegetables, especially Endive. There are many different methods in practice for growing good Endive, all of which possess some merit. The plan I find best is to sow seeds on a south border at the end of July. As soon as the plants are large enough to be transplanted they are placed out a foot apart on a well-prepared border in which the soil has been enriched by a fair dressing of well-decayed dung. A little soot is sprinkled around the young plants, and if slugs are troublesome a little lime also; likewise see that they do not suffer from drought. By the end of September, or first week in October, the best plants are ready for lifting and storing in cold frames for late supply. Early in September, however, those that are not considered fit to lift and store away are covered with an inverted flower pot, taking care to stop the hole with a plug of moss to exclude light, or by placing ordinary flat roof tiles over the plants of the curled section, and by tying a piece of bast around the broad-leaved kinds similar to the method employed for Cos Lettuce in order to blanch them. These come in for use until frost destroys them, when recourse is had to those in frames. After storing those in frames every advantage is taken of fine days to admit plenty of air by throwing off the lights and carefully removing all decaying leaves. We have a quantity of dry leaves stored away in readiness for blanching the Endive when necessary. The dry leaves are spread over a portion of the plants to the depth of from 8 to 10 inches, which will perfectly blanch the Endive without producing or accelerating decay of the hearts, as is too often the case with other methods employed. The varieties we prefer best are the Moss Curled and Improved Round-leaved Batavian.

CELERY.—This is a most useful vegetable, being suitable for stewing, flavoured soups as well as salads. I need not enter into details of its culture further than point out a few important points which must not be overlooked. To produce good Celery, then, it is of primary importance to pay strict attention to giving a proper supply of liquid nourishment when in a growing state; secondly, taking great care in earthing up to draw the leaves firmly and closely together with the hand, whilst with the other the soil is placed around the plants. If this be not done perfectly blanched examples of Celery cannot possibly be obtained. Thirdly, see that the tops of the ridges are covered with litter, or, better still, with boards nailed together at right angles to throw off the heavy rains of autumn and winter, otherwise the plants will be found rotten when lifting late in the season. I find the best varieties to be Major Clarke's Red, Ivory's Nonsuch, and Sandringham White.

BEET.—Every gardener grows this favourite vegetable. It may be had in use all the year round. It requires a deep rich soil for producing roots of excellent quality, and must also be lifted with great care from the open ground, otherwise its roots will be broken, and a consequent loss of colour will ensue. Beet should be stored in layers of sand in a cool shed or cellar, where it will keep fresh for a long period.

I have now enumerated and described the various vegetables useful for winter salads, together with brief notes on their cultivation. Some will say the Cucumber is omitted, but this was purposely done for this reason: It is rarely if ever used now as a constituent of a good salad; but Tomatoes often are, and they are certainly more wholesome. The object of these notes is to include such vegetables as will make an agreeable salad for daily consumption from September till May, and these are chiefly penned for the benefit of younger gardeners and inexperienced amateurs.—A HEAD GARDENER.

FLOWER SHOW SCHEDULES.

I WAS very pleased to see "A Mid-Sussex Gardener's" letter on the above subject, page 110, and I think with him that many schedules need revising, as he says the entrance fees are very large at some of the Sussex shows. There are two things which may be said in their favour—they prevent, to a great extent, inferior things being shown, and also anyone from entering recklessly; I mean by that, entering and then not taking the plants, thereby causing trouble to the stagers, especially if much space is required. What may be said against them? They prevent or check competition. I believe many good plants are left at home because of the separate entrance fee required. An exhibitor would probably weigh his chance thus—"They are not so good as A and B showed last year, and I will not risk entrance money for chance of third prize;" whereas if they had not to be paid for separately he would probably

say—"Well, there will be better there, but I may get a prize; and if I do not they are no discredit to me, and will help to make a show." I also think the entrance in the fruit classes is heavier than in the plant classes. Certainly the plants cost more to take to the show, but the prizes are generally better and less competition than in the fruit classes. I will instance the competition in some of the classes at the last Eastbourne Show. Morello Cherries, thirty fruits, prizes 5s., 3s. 6d., 2s. 6d.; entrance 1s.; nine competitors (not entries). Black Grapes, three bunches, 15s., 10s., 5s.; entrance 1s., ten competitors; and eight competitors in the class for white Grapes. Nine dishes of fruit, 20s., 15s., 10s.; six competitors, or thirty-three bunches of Grapes and forty-three dishes of other fruit for less than £2. Most of the fruit and cut-flower classes were well contested. That does not bear out my idea that separate entrance fees check competition, but it certainly prevented me from showing in five fruit classes. I think a small fee for each entry up to 5s., and afterwards free entry, is quite enough.

While on the subject I would like to mention the almost suicidal course pursued by the Eastbourne Gardeners' and Cottagers' Mutual Improvement Society, who made a rule last year to the effect that anyone residing outside the parish is not eligible to become a member of the Society. The entrance fees of this Society are excessive. At the Summer Show they range from 5s. to 1s. for non-members, and there are thirty classes provided for members only to which no entrance fee is prefixed. At the Chrysanthemum Show the entry is 2s. 6d. for the first, and 1s. 6d. for each subsequent entry for non-members. It is also worth noting that for twenty-four incurved blooms (open) the prizes were 20s., 15s., 10s. For twelve blooms (members only) the prizes were 15s., 10s., 5s., and the same for Japanese. I cannot think a Society so selfish as this will prosper. I think all shows should be open, but classes provided for the small growers, from which the larger ones are excluded, as at Liverpool; but even the Liverpool gardeners reserve many of the classes to themselves at their Summer Show.—J. GORE.

In your issue of February 7th, page 110, "Mid-Sussex" calls attention to the above subject. His very sensible article is, I think, well timed, especially his remarks on the schedule of the Brighton and Sussex Horticultural Society. It is to be hoped the Committee will take the hint and make some radical changes in their schedule, which is far from being up to the times. Having been an exhibitor of Grapes at their shows for a number of years, I have been astonished and disappointed year after year that they do not offer prizes for other sorts than Black Hamburgs and White Muscats that would make a good display at their September shows. They evidently think that Muscat of Alexandria is an inferior Grape, and more easily grown than Black Hamburg. The prizes for six bunches of the latter are invariably more than for six bunches of White Muscat, which is a mistake. The entrance fees are too heavy. I agree with "Mid-Sussex" that to adopt some system of membership would pay better and give more general satisfaction. The younger members of the fraternity in Brighton have succeeded in establishing a Chrysanthemum Society, and that their first show last November was a great success, must have been patent to all who had the good fortune to see it. I daresay the slight omission as to what constitutes membership will be rectified in the prize schedule for this year, and it is to be hoped that "Mid-Sussex" and others in the locality will join in and make their success more complete.—EXHIBITOR.

SHRUBBY VERONICAS.

OUR indebtedness to New Zealand and Tasmania for the many new and rare additions to our already large collections of garden plants can hardly be over-estimated when the surprising way in which some of them adapt themselves to our average English winter is taken into consideration. That much remains yet to be done in the way of fresh introductions before we can form an adequate idea of the richness of the vegetation in those countries is shown in the words of a popular writer, who, in reference to Tasmania in particular, says, "Somersetshire cannot surpass her orchards, nor Devon match her flowers;" and even in the handbooks of the floras the many plants we see described as exquisite garden plants that have not yet been introduced lead us to hope for not a few genuine surprises, and anxiously await the result of some enthusiastic and enterprising collector's researches.

Of the New Zealand plants already introduced shrubby Veronicas form a fair proportion, and are useful in many ways, among which the decoration of the rockery and to give variety to the mixed flower border are not the least prominent, some few also being specially adapted for pot culture, and when well grown are by no means to be

despised either as window or table plants or for the greenhouse. Their cultivation is comparatively easy, the principal object being to obtain well-furnished plants, which is by no means difficult, as they will stand any amount of pinching back without injury, and may be left to the discretion of the grower.

I have found stopping the shoots early in spring the most successful way of obtaining dwarf bushy plants, and it does not in the least retard their free flowering. It is always advisable to keep them in rather small pots, giving a top-dressing of stable manure or liquid water in small quantities to compensate for the restriction.

V. TRAVERSII.—This is hardy except in very severe winters, is free-flowering and of neat habit. It seldom grows more than 1 to

Fig. 28.—*Veronica elliptica* (*decussata*).

2 feet in height, and its large spikes of white and purplish flowers somewhat in the way of the well-known *V. Andersonii* are very attractive; they are produced in the greatest profusion, and last more or less throughout the summer. The leaves are of a lively shining green, and for this reason the plant is extensively used in some large gardens for greenhouse decoration, together with many other fine-foliage plants to intermix with spring flowers. It is increased from cuttings with the greatest ease in the ordinary way. A native of the Middle Island, where it is found abundantly.

V. SALICIFOLIA.—One of the most variable of all the *Veronicas*, and under cultivation runs into many forms. It is one of the principal parents of the many hybrids which we have in gardens, among the best of which are *V. kermesina*, *V. Lindleyana*, *V. Andersonii*, *V. versicolor*, *V. linariæfolia*, and many others, the merits of which are pretty well known and appreciated. The flowers are produced in the same way as the above, and are variable both in size and colour.

This is a desirable plant for the conservatory, and very useful for planting between *Camellias* in beds.

V. PARVIFLORA.—This seems to be only a small variety of the preceding, has little less than neatness of habit to recommend it to the general cultivator. It should, however, find a place where a collection is desired.

V. MACROCARPA.—Although the most showy and desirable plant this is perhaps the most rare in gardens. In habit it is similar to *V. salicifolia*, but from which, as well as the others, it is distinguished by its larger and more elegant flowers, and for these merits alone it deserves a place in every garden.

Of hardy species we have a much larger number to choose from, and no one that has them nestling among the stones in the rockery can doubt their usefulness or appropriateness for this purpose. Indeed it would be difficult to find another class of plants more suitable, and possessing the twofold quality of enlivening with their flowers, which if not very attractive are interesting through the summer, and of breaking the monotony of bare stones and rocks with their shining green or glaucous leaves during winter.

V. ELLIPTICA syn. *V. DECUSSATA*.—In favourable situations this attains considerable dimensions in the course of two or three years, on account of which it should be planted in bold positions with good backing. It has been confounded with *V. formosa*, but how I am unable to determine, the latter being a small-leaved species from Tasmania, while *V. elliptica* has large broad oval-shaped leaves and is very distinct. The flowers, which are produced in clusters, are white or purplish, becoming more intense as they grow older. Fig. 28 shows a small flowering branch of this plant.

V. DIOSMEFOLIA.—A dwarf bushy species seldom attaining more than a foot in height, although only of recent introduction, quite long enough to show its qualifications for this work. It has been appropriately named "The Rockery Gem," the numerous flowers covering the plant.

V. PINGUIFOLIA.—This is deserving of notice as a desirable plant if only for its bright glaucous coloured leaves. It is very neat in habit, and has long been confounded in gardens with *V. carnosula*, from which it is said to differ only in its hairy capsule, the other being glabrous; but apart from this, the leaves of *V. carnosula* are not nearly so glaucous, and are inclined to be oblong.

V. SALICORNIOIDES.—I am not aware that this has flowered in this country, although it has been cultivated for many years. It is a very much-branched prostrate-growing species, and resembles a miniature *Cupressus*, for which it has been repeatedly palmed off on the credulous. It forms dense masses, and although a partial shade-loving plant it is apt to damp-off if moisture be allowed to become stagnant near its roots. It is easily raised from cuttings placed under a bellglass.

Among others equally desirable are *V. lævis*, *V. amplexicaulis*, *V. anomala*, *V. chathamica*, *V. epacridea*, *V. Haastii*, and *V. ligustrifolia*.—M. S.

CHALK v. LIME RUBBISH FOR VINE BORDERS.

I HAVE no recollection of seeing chalk recommended for mixing with the compost for Vines but once, and then I felt doubtful as to its good effects, or whether the Vines would care to come in contact with it or ramble among it, until a few days ago when about to make a new Vine border along the front of a house which had been planted with Vines in the inside about three years ago. The front wall next which the Vines had been planted was on arches, which had been filled with bricks packed one on the other, but no mortar used, and on the outside of these was packed a quantity of chalk as a further means of keeping back the roots, and as all this had to come away to admit of the new border it was found that the roots were rambling amongst the chalk and clinging to it with small fibres till the apertures between the chalk were a network of roots. This I took for granted that the Vines have no objection to chalk, but rather a liking for it, and as I have considerable difficulty in getting lime rubble for the purpose named I intend to use chalk instead. Probably there are many situated like myself at a distance from any place where much building is going on, and who have chalk close at home, and would be glad to avail themselves of it if they could put confidence in the results.—C. W. C.

HAREFIELD GROVE, NEAR RICKMANSWORTH.

THE seat of George Webster, Esq., is now a monster glass establishment. Somewhere about seventy houses, many of them of a considerable size, are devoted to horticultural purposes, all produce beyond the wants of the family being sent to market. French Beans, Tomatoes, and Melons are grown in enormous quantities. Six span-roofed houses, each from 100 to 110 feet in length, are used for growing Cucumbers. Grapes are extensively cultivated here, fifteen houses of various sizes being devoted to them, some of them being of a large size. There are also good Peach houses, and several

thousand pots of Strawberries are forced annually. Plants for supplying cut flowers are extensively grown, and Gardenias are grown to perfection and in quantities. There is a large stock of very fine specimen plants of *Eucharis amazonica*, which were in full bloom recently, and *Richardias* are grown in great number. Roses under glass are similarly abundant—a large number are planted out, and about 3000 plants are in pots. The kitchen garden and orchards are extensive, a new fruit garden of about 15 acres being added a year since, in which 50,000 fruit trees and bushes were planted. This will soon be one of the wonders of Harefield, and it is in contemplation to still further extend it. The pleasure grounds are pleasantly situated, and one of the largest lawn tennis grounds in the kingdom has just been laid out and planted. Harefield is easily reached from London *via* Watford and Rickmansworth, and is about a mile and a half from the latter station, and close to Moor Park and other celebrated horticultural establishments. Mr. John Gough, formerly head gardener to Lord Hampton, is in charge of Harefield, and a very large proportion of the glass has been erected under his supervision. —W. D. W.

CHATSWORTH.—We have authority for stating that MR. OWEN THOMAS of Impney Hall Gardens, Droitwich, and previously for several years head gardener to Sir Robert Peel at Drayton Manor, has been appointed to succeed the late Mr. Speed at Chatsworth. Mr. Thomas is a highly skilled gardener, and we have not a doubt that he will maintain the fame of the great gardens to which he is appointed and his own well-won reputation. He has on several occasions enriched our columns, and was the originator of Mr. Wright's work, "Mushrooms for the Million," that has had such a large sale since its publication.

— AMONGST the sums received during the week for the benefit of the family of the late MR. ALEXANDER HONEYMAN, Mr. Wright desires to acknowledge thankfully a donation of £1 from the assistance fund of the Edinburgh Horticultural Association. "A Devon Gardener," "A Camberwell Gardener," "W., Abergavenny," "Old Gardener," "J. R., Leeds," "A Working Gardener," "W. J., Kendal," and "A Dorking Gardener" have also sent contributions, which could not be acknowledged by post. Mrs. Honeyman and family have returned to Scotland. The expenses of the journey, with those attendant on the illness and interment of our lamented friend, having been met, any additions to the surplus will be gratefully acknowledged. The case is clearly before the public, and requires no special pleading. Of the five children left quite unprovided for the eldest is only nine years of age. Mr. Wright hopes to raise £15 more, and will then feel, for the present, that he has done his duty in this exceptionally painful case.

— AS a remarkable example of the MILD WINTER a correspondent sends the following—"Mr. Chas. Falkner of the Slough Hotel, Pershore, cut a branch off a Gooseberry tree on Thursday last with berries on as large as small peas, and strange to say red spider was noticed on the trees."

— MESSRS. E. WEBB & SONS, Wordsley, Stourbridge, send us a few flowers of some brightly coloured CYCLAMENS, of good size and excellent in form, the petals broad and rounded. Purple, red, pure white, and red and white, are the colours represented, the last-named being very pretty.

— THE BURY ST. EDMUNDS AND WEST SUFFOLK HORTICULTURAL SOCIETY SHOWS for the present year will be held upon July 3rd and September 11th and 12th in the Farnham Park and the Corn Exchange respectively.

— "CULTIVATOR" writes respecting the IMPROVED ROUND-LEAVED BATAVIAN ENDIVE as follows:—"I have a very high opinion of the above Endive, but your correspondent 'J. M.' appears to think it hardier than any other variety, but such is not the case in the north of England. The ordinary Batavian Endive has proved hardier here, and will stand more frost and rain; in fact, it should be grown in every garden as well as the above variety, more especially in localities where the rainfall is heavy and frost often severe. The rain

and damp atmosphere prove more detrimental to both varieties than dry frosts. I can confirm all 'J. M.' says in relation to its quality, for no other variety is equal to it in tenderness and flavour."

— THE remarkable SPECIMEN CYCLAMEN shown by Mr. J. Wiggins, gardener to W. Clay, Esq., Grove Road, Kingston, at Kensington last week, is one of the finest that has ever been exhibited, and well merited the cultural commendation awarded for it. The plant is about seven years old, and was growing in a 9-inch pot, the corm being quite concealed by the leaves, flowers, and buds. The specimen was in wonderful health, with strong beautifully marbled foliage, and over 300 flowers and expanding buds. The variety, which is named General Gordon, is of excellent habit, the flowers pure white, of moderate size, but very freely produced; and a number of younger plants, seedlings from this, exactly resemble their parent in these characters.

— A GOOD daughter of a good gardener sends the following note on the ANNIE ELIZABETH APPLE:—"My father wishes me to write you a line, while he smokes his pipe, to say that we consider Annie Elizabeth the finest cooking Apple on the earth." The specimens accompanying the note were very firm, and when cooked brisk and excellent.

— THE ROYAL CALEDONIAN HORTICULTURAL SOCIETY'S EXHIBITIONS will be held in the Waverley Market, Edinburgh, on April 2nd and 3rd, July 9th and 10th, and September 17th and 18th. At the first Show £350 are offered in prizes, forced plants forming the leading features. At the second £256 are offered for miscellaneous plants, cut flowers, fruit, and vegetables. Prizes amounting to £270 will be given at the Autumn Show, fruit being largely provided for.

— MRS. R. B. DODGSON, widow of the late R. B. Dodgson, Esq., of Beardwood near Blackburn, whose collection of Orchids was one of the finest in Lancashire, died last month, having survived her husband little more than a year, made many very large bequests to public institutions, and among the rest £500 to the Gardeners' Royal Benevolent Institution.

— THE annual dinner of the HORTICULTURAL CLUB took place on Tuesday last, and was numerously attended. The chair was taken by Mr. John Lee, Chairman of the Committee, and amongst those present were Dr. Hogg, Rev. F. H. Gall, Rev. Th. Flintoff; Messrs. J. D. T. Llewelyn, Shirley Hibberd, Harry J. Veitch, George Deal, J. F. Strange, C. P. Wheatstone, Herbert J. Adams, J. S. Cousens, Ch. F. Druery, H. W. Slottentoff, &c. It was announced that the Club had during the past year subscribed ten guineas to the Gardeners' Benevolent Institution, and that the following gentlemen had been elected members of the Committee in lieu of four who had retired according to rule—Messrs. Shirley Hibberd, Harry Turner, Ch. F. Druery, and the Rev. Theodore Flintoff. A report was agreed on, and will shortly be issued.

— A CORRESPONDENT informs us of a case of MUSHROOM-GROWING UNDER NOVEL CIRCUMSTANCES in the following words:—"Tell Mr. Wright I lent my copy of his work on Mushrooms to an old man, and he has now Mushrooms growing under the table in his room. He has cut one dish, and will have others as the crop is coming on well, now eight weeks after spawning. He has another box in his cupboard on the bottom shelf amongst the china, and evidently means business." The "old man" will at least have home-grown Mushrooms, and we hope he will enjoy them.

— VERY distinct and attractive in Mr. Major's greenhouse at Croydon are some strong-flowering plants of VELTHEIMIA VIRIDIFOLIA, the stout Tritoma-like spikes (18 inches high) bearing a number of rosy flesh-coloured flowers. The stems, springing from a mass of rich deep shining green foliage, have a telling effect among Hyacinths and other spring flowers, and similar examples could not fail being admired in conservatories in which they might be so easily produced. This good old, yet seldom seen, Cape bulbous plant succeeds in cold frames during the summer, and flowers freely in a greenhouse temperature at this period of the year. Strong plants well grown form very large bulbs, and produce offsets freely. A number of spikes are produced from the plants in 8-inch pots, and the flowers continue in beauty for several weeks.

— THE ROYAL BOTANICAL AND HORTICULTURAL SOCIETY OF MANCHESTER will hold their annual national Exhibition in the gardens

at Old Trafford from May 30th to June 6th. The prizes are very liberal in seventy-nine classes, especial prominence being as usual accorded to Orchids, to which eight classes are devoted, the total amount of prize money in these being £156. Stove and greenhouse plants, Ferns, fine-foliage plants, Perlargoniums, hardy plants, Roses, Clematises, miscellaneous plants, and fruit being well provided for.

— A BRISTOL correspondent writes:—"A few years ago there was in the gardens under my charge a good-sized bush of the female *GARRYA ELLIPTICA*, most unfortunately placed, being much overgrown by other things. Finding that it was extremely rare, I cleared away round it. It grew very well for a couple of years, and fruited, but from some cause or other, which I never could quite understand, it suddenly died. Fortunately I had put in a few cuttings, and had, when the old specimen died, two good plants. These I planted out the year before I left. They should by this time be getting to a good size. I also raised a batch of seedlings. Mr. Wm. Garaway, of the firm of Messrs. Garaway & Co., told me that nearly all the seedlings came male. Perhaps 'J. S.'s' plant is from Messrs. Garaway's stock. They have raised a large number from the plant above-named years before I knew the place. If 'J. S.' desires to raise plants from his seed he must wait patiently for their appearance, they take a long time to germinate. I could send you a bunch of fruit (dry, but not pressed) if you wish." We shall be obliged to our correspondent for the specimens offered.

— "VISITOR" writes:—"I observed at the last meeting of the Royal Horticultural Society at Kensington a plant shown by Mr. B. S. Williams under the name of *JAMBOSA ACIDA*, which appeared to me to bear an exceedingly close resemblance to *Grias cauliflora*, the Anchovy Pear, an effective, handsome, but little known tree from Jamaica."

— THE National Auricula Society's Southern Show is to be held at Kensington on April 22nd, and the National Carnation and Picotee Society's Show on July 22nd. Veitch Memorial medals and prizes of £5 will be offered at the first named for twelve show distinct Auriculas (amateurs and gentlemen's gardeners), and at the last for twelve Cartons (excluding selfs) and six Picotees. The substantial balance of £26 15s. 2d. has been secured by the Carnation Society, the Auricula Society having £6 8s. 10d. in their favour.

— MESSRS. BARR & SON, King Street, Covent Garden, send us a specimen plant of *MAY'S NORTHAU BRUSSELS SPROUTS*, a variety of very fine appearance, which has been frequently successfully exhibited by the raiser, Mr. May, The Gardens, Northau House, Barnet, and at the last Show of the Borough of Hackney Society at the Royal Aquarium his specimens of these Sprouts were much admired. The sample under notice is 2½ feet high, the stem for 1 foot 8 inches of its length being covered with closely packed firm sprouts from 1 inch to 1½ in diameter. It is evidently a useful form of this important vegetable, and is very tender and of good flavour when cooked.

— A VISITOR to the NATIONAL AGRICULTURAL AND HORTICULTURAL EXHIBITION AT PARIS, which opened on the 11th inst., and continued until the 20th inst., states that it included a very large quantity of field and garden produce, such as grain, vegetables, fresh and dried fruits. A pretty display of flowers was also provided, and added much to the beauty of an extensive exhibition, which filled many rooms in the Palais de l'Industrie.

— MR. CHARLES WHITEHEAD'S essay on PROFITABLE FRUIT FARMING, published by Messrs. Longmans, Green & Co., contains matter of great interest to cultivators of hardy fruits either on a large or small scale, and it is commended to the attention of all who are interested in this important subject. That there is still a market for home-grown fruit is evident from the statement of the author that "only about 29,000 acres have been added to the acreage of fruit land in the United Kingdom during the last eleven years; or 190,710 acres in 1883, as against 160,857 acres in 1872. The annual average amount of raw fruit imported into this country since 1875 is close upon 4,000,000 bushels. The annual average produce of the English fruit land may be estimated at something like 9,000,000 bushels, making with the imported raw fruit a total of about 13,000,000 bushels of fruit available for the United Kingdom. From this amount at least 3,000,000 bushels must be deducted in respect of the Apples and Pears grown upon the orchard land, which are supposed to be used for cider and perry making; and this would leave only 10,000,000 bushels of raw

fruit for the consumption of the 35,246,562 inhabitants of the United Kingdom, to make all the jam, and to supply all the fresh fruit for puddings and pies, and all the fruit that is eaten raw by the whole community, to say nothing about the large quantity of preserves and preserves, lozenges, extracts and essences for home use and for exportation."

— MR. WILLIAM MARRIOTT writes:—"The Council of the Royal Meteorological Society have arranged to hold at 25, Great George Street, S.W., by permission of the President and Council of the Institution of Civil Engineers, on the evening of March 19th next, an EXHIBITION of THERMOMETERS; I am therefore instructed by the Exhibition Committee to invite co-operation, as they are anxious to obtain as large a collection as possible of such instruments. The Committee will also be glad to show any new meteorological apparatus invented or first constructed since last March, as well as photographs and drawings possessing meteorological interest. Should any persons be willing to co-operate in the proposed Exhibition, I should be obliged by their furnishing me (by March 1st) with a list of the articles they will be able to contribute, and an estimate of the space they will require."

— "M. S." writes:—"Surpassing in beauty the old and well-known *Dentaria digitata*, *DENTARIA POLYPHYLLA* is a welcome visitor at this early season, and a great acquisition to our spring-flowering plants. Dwarf in habit, it is seldom more than from 4 to 6 inches in height. The flowers which terminate the branches are creamy white, and are borne in clusters, reminding us of the *Arachis hypogaea*, as they are formed underground, and unless the plants are strong, are often spoiled before they push through. A good loamy soil in a sheltered situation suits it admirably."

— THE "BOTANICAL MAGAZINE" for February contains plates of the following plants:—*Nymphaea alba* var. *rubra*, an extremely pretty Water Lily, with bright rosy-red flowers, which Sir Joseph Hooker thinks will be greatly improved under cultivation. *Tilia petiolaris*, a species resembling the White Lime, and known under the names *T. americana pendula*, *T. alba pendula*, *T. platyphylla pendula*, and *T. argentea pendula*. It is quite hardy and produces its fragrant flowers in July. *Pentstemon labrosus*, a Californian species with small scarlet flowers and very narrow leaves. It was found by Dr. Rothrock "during Wheeler's expedition in 1875 in Mount Pinos, south of Tejou, at an elevation of 7000 feet, and introduced to this country by Mr. W. Thompson of Ipswich, with whom it flowered in August last year." *Gladiolus Quartianus*, though this is described as having a claim "to take rank amongst the finest species of the genus," it is, judging by the plate, scarcely satisfactory in a horticultural point of view, the flowers being dull yellow streaked with red. The first specimens received in England were sent by Sir John Kirk a short time since, and flowered at Kew last October. *Masdevallia Schlimii*, a beautiful species, discovered in 1847 by Louis Schlim, half brother of M. Linden, but not introduced until recently by Messrs. Sander & Co. of St. Albans. The flowers are yellow, mottled and spotted with reddish brown, the tails yellow and 2 inches long. It is free-flowering, bearing scapes of four or six blooms. *Notospartium Carmichaeliae*, a very distinct member of the Leguminosæ, known in New Zealand as "Pink Broom." It forms a leafless shrub or small tree 20 feet high, with slender drooping branches bearing short racemes of small purplish flowers.

— INTERNATIONAL HEALTH EXHIBITION.—Preparations for the holding of this Exhibition at South Kensington are proceeding rapidly. The Board of Trade have certified that the Exhibition is an International Exhibition, and exhibitors thereat will accordingly participate in the privileges accorded by the Patents, Designs and Trade Marks Act of 1883. The officers of Her Majesty's Customs have also announced that the Lords of the Treasury have consented to the buildings being considered as a bonded warehouse during the continuance of the Exhibition, as was the case at the late Fisheries Exhibition. The General Committee now numbers nearly 400 members, and from these seventeen Sub-Committees have been formed. These have all been doing valuable work in advising the Executive Council as to the nature of objects which it is desirable should be fully illustrated, in obtaining the co-operation of many persons of eminence in the various branches on which the Exhibition will treat, and in supervising the applications for space. The allotment of space, which has been largely applied for, is being rapidly proceeded with, and applicants will soon be informed of the

decision of the Executive Council with regard to their applications. In response to a request made by His Royal Highness the Prince of Wales, President of the Exhibition, the eight Water Companies of London have resolved to exhibit, in a pavilion which is being erected for them, their appliances for the supply, filtration, &c., of water, together with diagrams showing the various processes and localities; and a powerful Sub-Committee, under the active chairmanship of Colonel Sir Francis Bolton, has been formed to carry out this branch of the Exhibition. The Water Companies have also determined to put up in the grounds a large fountain, which will be illuminated at night by electricity. This fountain of light will, it is anticipated, materially add to the beauty of the illumination of the gardens. It is impossible as yet to give any definite information with regard to foreign countries; but, so far as one can judge at present, Belgium, China, and India will be the best represented. A Royal Commission has been appointed in Belgium, and the Consul-General in London is their active representative here. To China has been allotted the space which it occupied last year at the Fisheries Exhibition, and a Chinese tea garden, restaurant and shop will not be the least interesting objects in the Exhibition. India is to be adjacent to China, and strenuous exertions are being made to secure the united action of many of the principal Tea-planters in India, so as to insure a good and representative show of the Indian Tea-growing industry.

HARDY PLANTS IN FLOWER.

SNOWDROPS.—Nothing is more pleasurable than commencing these notes with these charming offspring of the early year, for I cannot boast of having varieties which in the late months of the dying year, although such there are. The late Rev. Harpur Crewe possessed many varieties of *Galanthus nivalis*, the earliest of which commenced to bloom in October, and others kept up the succession till March—five months of Snowdrops! Happily the collection of the reverend enthusiast has passed into the kindly keeping of another ardent lover of hardy flowers, and we are sure they will be well cared for, and trust in due time will be distributed, but of course many years will elapse before many of us can hope to cultivate the entire series. *G. nivalis*, the common species, is very variable in size, form of the perianth division, and leaf size; but as far as I have examined all are characterised by the green inside of the inner divisions and the green blotches at the back of the upper part of the same without the green at the base so characteristic of *G. Elwesi*; but as I have not examined all the varieties, but it will not do to designate this as a hard-and-fast characteristic.

Galanthus Elwesi.—This is in my opinion as pretty as any Snowdrop in cultivation. Several years since, when first introduced by the enthusiastic bulbophile in whose honour it is named, I noticed two or three plants in flower at Kew, and was struck with its distinctness—the globular form of perianth with brown segments, the distinct green blotches at the base of the inner divisions, and rather broad short glaucous leaves. Mr. Elwes is quite disappointed with what is now under cultivation when compared with what he saw when the species was discovered, and he thinks it degrades in our English gardens. It may, but I think not—i.e., the true form; but dealers have collected thousands of bulbs regardless of character, the majority of which are very poor forms of it. I have lately seen a bed perhaps of two thousand bulbs, and noticed how few were really the typical *G. Elwesi*, which was distinguishable by its precocity, longer and more globular flowers with a stouter consistency, and these stood head and shoulders above the rest. I still have hopes that this beautiful Snowdrop will hold its own.

G. plicatus—the Crimean species—is very fine, a strong grower, with flowers combining the characteristics of *G. nivalis* and *G. Elwesi* and longer than either, but most easily distinguished by the broad plicated leaves. I am sure this as well as many other bulbs require to be planted deeply. I pulled up a peduncle the other day which measured 18 inches in length, equal distances above and below the surface of the ground, and the batch from which this was taken is very vigorous and healthy.

G. Imperati.—Though generally regarded as a distinct species is certainly nothing more than a strong-growing variety of *G. nivalis*, but nevertheless most desirable, producing flowers as large as any I know, and a clump of it is an ornament of no mean value.

G. Redoutii.—Superficially this is very distinct, chiefly in the foliage. The flowers appertain to *G. nivalis*, but the leaves are unique as far as I know, a Snowdrop looking more like a Leu-

coium, long and broad, of a deep shining green colour, not at all glaucous; the flowers are comparatively small and thin in texture. It is well worth growing.

COLCHICUM MONTANUM (syn. with *C. bulbocodioides*, Bieb.).—This is a desirable little species, as it flowers now instead of with the majority of its congeners in the autumn; and another peculiarity is the leaves precede the flowers. The former are about 4 inches long, deep green, slightly glaucous, oblong-lanceolate in form; perianth 3 to 4 inches high; the limb segments about an inch long, oblong, at first nearly white, changing to pale pink: when expanded the flowers are from 1½ to 2 inches across. It came to me under the name of *C. Bertoloni*, a species I am unacquainted with. If some reader of the Journal could inform us whether this is also a synonym of *C. montanum* good service would be done. I like the plant very much, a good tuft has been in flower some time.

SCILLA BIFOLIA.—This is, I think, one of the smallest of the Squills, flowering so early in the year, and when the bulbs get thoroughly established they send up dense tufts of the starchy blue flowers, any spike of which is good enough to arrange in a buttonhole or hair ornament. But the variety *alba* claims first rank for this purpose, its delicate small racemes of pure white flowers being very desirable. It is certainly a gem of the first water, but is rather later-flowering than the type. My bulbs will be quite three or four weeks later. There is a variety named *grandiflora*, also another named *corymbosa*, both of which are now in flower. The form has longer and more crowded spikes of flowers which are of a rather deeper shade of blue, while the latter has corymbose spikes of thickly set flowers of the same colour as *grandiflora*. Both these varieties are very desirable, but in my opinion do not equal *alba*.

S. AMENA.—This is but a variety of *S. sibirica*, which it resembles very much, and is generally distributed with that species, but it flowers much earlier, and is a rather deeper blue than *sibirica*. It is now in full flower, whereas the latter is only just peeping above ground and will not be in flower for a month or so. In a larger batch I have, all of which were supposed to be *S. sibirica*, numbers of them are in full flower, dotted here and there all over the beds. It is desirable on account of its earliness, more particularly as it is not superior to *S. sibirica*.

ERANTHIS HYEMALIS (the Winter Aconite).—Although common this is a bright little gem, and should be very extensively planted in the wild garden, woodland, near the margins of lakes, and in shrubberies, as it lights up the surface with its sheen of golden blossoms and bright greenery. Curtis in his time thought it worth a place in the pages of his "Botanical Magazine," a figure of it appearing in vol. i., fig. 3, under the name of *Helleborus hyemalis*.

IRIS RETICULATA.—This is just opening its first flowers, while the variety *Krelagei* is nearly past. I had two large clumps of the latter, each with about a score or more flowers, and a charming picture they have been, but not so deep in colour as the type, which after all is my favourite. I have a clump which will have at least thirty flowers of that rich deep violet-purple colour with golden marks at the upper part of the divisions—a charming and very effective contrast, the flowers smelling strongly of Violets. If I grew but one Iris I think it would be this; it comes at a period of the year when the garden is usually far from enjoyable, which makes it all the more welcome to some, and it is so lovely and distinct. It requires to be planted deeply—quite 8 inches, in rich light sandy loam, and to remain undisturbed for years.

LEUCOJUM VERNUM (the Vernal Snowflake).—A very beautiful little plant, and when seen in broad masses is very attractive. It grows about 6 inches high. The peduncles are one to three-flowered, most frequently with but one flower, drooping, about 1½ inch across when expanded, with six nearly equal perianth divisions, white, with a dorsal yellowish green blotch at the apex of each; very useful for cutting and forcing. Who has seen the double-flowered *L. vernum*? If any of the readers of the Journal can give testimony as to its actual existence I shall be happy to make a note of it and hope on, for I have two bulbs which were bought on the continent as the double variety, which up to the present have refused to produce flowers, although treated liberally.

DORONICUM PLANTAGINEUM EXCELSUM.—Such is the name which I hope is generally received for this plant, resulting from the efforts of the Rev. C. Wolley Dod to establish for it a permanent name. Last year it was freely circulated by a firm under the name of *D. hybridum*, but I fancy the same firm is offering it under the name of *D. draytonense*, favouring the place where it originated. I hope my surmise may be wrong, for nothing is more misleading than the multiplication of different

names for the same plant. It is certainly a variety of *D. plantagineum*, and the name *excelsum* is very applicable. Several flowers are expanding, and it will be in bloom from the present time till late in the summer, and it will force splendidly; indeed one may enjoy it through nearly all the dull winter months if properly handled. The large bright yellow flowers are so effective at all times, and it grows so freely almost anywhere, that it constitutes one of the best hardy perennials in cultivation.—T.

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 12TH.

SCIENTIFIC COMMITTEE.—Sir J. D. Hooker in the chair.

Cuscuta Trifolii.—Mr. W. G. Smith exhibited young Clover plants with seedling specimens of this parasite just commencing to twine themselves about it; some had the seed skin still attached to the radicle. He observed that, while some seeds germinated in a few days, others required months.

Mushroom Spawn.—Mr. Alfred Bennett read a communication bearing upon certain difficulties of introducing the French system of growing Mushrooms in underground quarries. It was referred to Mr. Berkeley for report.

Electric Light on Plants.—Mr. Boulger called attention to a paragraph in *The Garden* referring to experiments by Mr. R. Cross on Potatoes germinating under the electric light alone, being kept in the dark during the day. Under these circumstances it was asserted that no chlorophyll was produced at all.

Hyacinths Growing in the Dark.—Mr. Smee showed a bulb which had germinated in the dark after being left in it for two years, and a malformed blossom of *Zygopetalum Mackayi* in which the lip had been arrested.

Stanhopea, Hardy.—Hon. and Rev. Mr. Boscawen informed the meeting that he had placed a plant in an open cold shed. It withstood 13° of frost in November and again in January, and now is in a most healthy condition.

Diseased Pear Stem.—Sir J. D. Hooker exhibited a stem of a Pear received from Belvoir Castle with an injured surface. The bark is smooth and wood dead. The opinion of Mr. Berkeley and Sir J. D. Hooker was that the appearance was due to excessive heat, being sunburnt.

New Species of Potatoes.—Sir J. D. Hooker showed drawings of the two new species of Potato prepared from the *Botanical Magazine*—viz., *Solanum Maglia* from Chili, and *S. Jamesi* from Arizona. Remarks were made on semi-naturalised condition of Potatoes in various parts of Scotland, as Clova, Glenesk, and Glenshee. In some places, according to Mr. Loder, the Potatoes had been growing for forty years after the departure of the original inhabitants, but crops were habitually taken from them.

Lenzites gibba var. tenuior.—Mr. Berkeley exhibited a fine specimen of this fungus growing from a Beech stump. It is usually much thicker, but it has grown with a thin structure from its habit. It was received from St. Leonard's Forest.

On the Spore-retaining Power of Sand.—A communication from Mr. Plowright was read on this subject, containing a criticism of Mr. W. J. Smith's examination of sand (*Gardeners' Chronicle* of Feb. 2, p. 153), in which the gentleman gave a fig. of a grain nearly 2½ inches in length, representing a multiplication of 40 diameters. Hence the grain is nearly 1-16th of an inch, but described as of extremely fine sand. Mr. Plowright maintains that it is the size of the interstices that is of importance, not the grains. Experiments were made with sand in tubes, and the excellence of that material as a filter depends upon the fact that the water causes the larger grains to subside first, and the smaller subsequently fill up the interstices. The wedging takes place only at the uppermost part. Experiments were detailed showing that neither a heavy powder, as red lead, nor a light one, as lamp-black, were allowed to pass through. Similarly with water charged with *Ustilago*, so much so that it resembled ink, none passed through; and finally, water charged with Potato spores filtered through and upon fresh slices of Potatoes; the latter, however, were not diseased, though certain specimens treated with water so charged became diseased.

Further Observations of Mr. Jensen upon the Potato Disease.—A long communication was received from the same gentleman dealing with the following matters: (1) Rapidity with which the disease spreads. (2) Early disease, a small crop; late disease, a large crop. (3) Influence of temperature upon the disease. (4) Can we do anything to retard the outbreak of the disease? (5) Is the foliage more susceptible to disease when the plants have attained a certain stage of development? (6) The spread of the disease in Nature. (7) Hybernation of the disease. The whole of this communication will shortly appear in the *Gardeners' Chronicle*.

Circumnutation in Root Hairs.—The Rev. J. Henslow showed drawings by Mr. Saunderson, of Ealing, of roots of *Poa pratensis* growing in water, the abundant root hairs of which showed remarkable coils and spiral twisting. He observed that pollen-tubes grown freely will twist in a similar manner.

Plants Exhibited.—*Galanthus nivalis* vars.—Mr. Loder showed the following vars.: *lutescens*, *angustifolius*, *poculiformis* fl.-pl., *Imperati*, *plicatus*, *Elwesi*, *Redoutei*. He also exhibited *Crocus Imperati* var. *albiflorus*. Dr. Lowe observed that it had been heard of in Italy, but not known for 105 years. He, however, discovered one plant amongst a patch of the purple form, about thirty miles from Naples, at Tocarna. Mr. Loder also showed *Crocus ochroleucus* and *C. Balansæ*, as well as a finely grown specimen of *Musa Ensete* in flower, though only one year old. He observed that it flowers and seeds in the south of France.

SPECIAL SOCIETIES.

It seems to me that I have become involved in a larger correspondence than the necessities of the case as it was first put required. A correspondent found fault with the schedule of the National Auricula Society, and I sent him a copy through the Editor, thinking he might be able to make some suggestions for the improvement of it. He made no suggestion that I could bring before the Committee. Then came the usual bud of anonymous correspondents, imputing interested motives to

members of the National Societies in general and your humble servant in particular.

To make this matter clear we must go back about twelve or fourteen years, to the time when the Metropolitan Floral Society was founded. The Rev. H. H. Dombrain was Secretary. At that time the Auricula was almost an unknown plant. Mr. Dombrain, Mr. James, and a Mr. Butcher were the only growers near London. I was a subscriber to that Society, although I grew no Auriculas or Carnations. The prizes offered were of course divided between Mr. Dombrain and Mr. James. I did not complain of this; no complaint was made by anybody. Interested motives were not thought of. However, I was urged to take up the Auricula. I did take it up, and in a year or two I beat Mr. James and Mr. Dombrain; and, although I only grew a three-light frameful of plants, I beat Mr. Charles Turner of Slough for the best fifty at the Royal Aquarium. It was now thought that the best thing to do was to break up the Metropolitan Floral Society, on the ground that "florist flowers were at a discount in the south." I could see other growers taking up the culture of the Auricula, and was not satisfied that the whole thing should be brought to so abrupt a termination. Being at one of the northern shows at Manchester a few years later, in company with my esteemed colleague Mr. Dodwell, we were urged to resuscitate the exhibitions in the south. We did so, and the National Auricula, Carnation, and Picotee Societies are the result.

I must, by leave of the Editor, enlarge on another subject, and that is the selling of plants. I did not raise this question; but my name has been so mixed up with it, especially at page 128 by "Fair Play," that it does seem to me at least that there is some ulterior motive behind this. I can fancy the thought may occur to some persons' minds who are anxious for "fair play." "Here is Douglas, a gentleman's gardener, making a rare good thing by selling his master's plants. Surely this is wrong, let us give his employer a hint." It is very kind of your correspondents, and quite right that they should look after other people's business, especially if they have none of their own to attend to. Well, if it pleases them it does not hurt me. Quite recently I stated in this Journal that I did not sell Auriculas nor Carnations and Picotees, and why did I do so? "D., Deal," gave a short report of Mr. Penson's Auriculas, and stated that they were supplied principally by Mr. Douglas. I had no hand whatever in forming Mr. Penson's collection, except that I let him have two plants which he had some difficulty in obtaining. They were the first and the last plants I ever supplied him with. "D., Deal," did not think it worth while to write to me and apologise for hurting my feelings. Considering the way some of your correspondents under the cloak of a *nom de plume* write about me, one would think I had no feelings to hurt.

In 1882 Mr. Cannell had our surplus Carnations, and this year Mr. Turner had them. If the information is of any use to your readers—I opine it is—may I further trespass on your kindness to say that I cannot supply any plants of my new Auriculas, *Silvia* and *Conservative*? They will be placed in the hands of Mr. Turner of Slough for distribution on the 1st of May next. I must repeat again, in answer to "Auricula," that I have no control over exhibitors. They must conform to the rules of the schedule, which has been drawn up and carefully revised by the Committee. I may also say that the shows will be held as usual under the auspices of the Royal Horticultural Society on the 22nd April and 22nd July respectively. The schedules will be published immediately.—J. DOUGLAS, *Great Gearies, Ilford*.

[We are fully convinced that not one of our correspondents had the slightest thought that Mr. Douglas was acting unfairly towards his employer; and as to conveying intelligence of that nature in the manner and with the object indicated, the supposition falls to the ground in face of the fact that Mr. Douglas's surplus plants have been publicly advertised for sale by a florist. When Mr. Douglas announced that he did "not sell Auriculas" he intended, we presume, that he did not do so in a retail manner to amateurs. If he had said so at the time, or stated what he states now, that he disposed of his surplus stock to florists, no misunderstanding could have arisen. He is perfectly justified in doing this with the consent of his employer, and we are quite satisfied that he has that consent in all his transactions in growing, exhibiting, and disposing of plants.]

HOW PLANTS OBTAIN THEIR FOOD FROM THE SOIL.

ON page 49 of the Journal "Querist" in his "Advice to Young Gardeners" says, "I do not suppose the average young gardener knows what the various manures are composed of, or in what way they are beneficial to plant life; nor yet perhaps do they know how plants obtain their food from the soil." If such be the case it cannot be out of place to bring such important questions before the notice of young gardeners who are constant readers of the *Journal of Horticulture*. I will, therefore, endeavour (as an under gardener) to answer the questions put by "Querist," as far as my knowledge will permit me. I purpose, however, first to show how plants obtain their food from the soil, and afterwards to show how that food can be added to the land by the application of manure.

First, if a plant is burnt we find part passes off in vapour and smoke, while another portion remains as ash. Thus we have two distinct classes of elements and compounds—volatile matter, and non-volatile substances. The volatile elements are oxygen, nitrogen, hydrogen, and carbon. The others are silica, lime, potash, soda, magnesia, and iron oxides, combined with phosphoric acid, carbonic acid, and sulphuric acid.

These elements and compounds found in a plant must have been supplied to it in its food, and this food is chiefly obtained from the soil in which the plant has grown. A soil may, however, contain large supplies of every substance which a plant requires, and may still be unable to yield them, because it is not in a condition available as food. Nothing is of any service as plant food unless it will dissolve in rain water, as a plant cannot take up anything in a solid state—it must be in a state of solution. Those portions of the soil, therefore, which can be dissolved in rain water are known as active, whilst those which will not dissolve in rain water are termed inactive. It is the active portion which is of immediate use to us as plant food, as it is in a state of solution, and is readily taken up by plants to nourish and support them.

The inactive portion, however, is not valueless in our soils, as it is quite possible to make it take an active form. It can be done by thorough cultivation of the land, for, as we all know, by exposing soil to the action of air and frost it is broken into a fine condition, which increases the amount of surface. Rain water can then pass through and into the soil, which, with its oxygen and carbonic acid together with the atmospheric agencies, will perseveringly bring that matter into solution, when it can be used as plant food; so that the inactive matter really preserves plant food, which can be called upon by the use of atmospheric agencies, and be equivalent to the addition of so much manure. This solution is then taken into the circulation of the plant through the small rootlets, which are constantly in search of food. A small portion of the organic matter is, however, taken in from the atmosphere, but as so much is absorbed from the soil we see the importance of adding to our soils plant food, which we do in the form of manure, upon which I purpose to speak at a future time.—UNDER GARDENER.

MR. ALEXANDER HONEYMAN.

IN accordance with our intimation of last week we publish a portrait of this accomplished gardener and striking and instructive writer, with an outline of his life. This we are able to do in the form of an autobiography, and under rather singular circumstances. About four years ago, and after having recognised his ability as an occasional contributor to our columns, Mr. Honeyman was invited to fill a vacancy on the staff of this Journal. Desirous that we should know something of his character and antecedents he sent the communication which we now publish. Under ordinary circumstances the letters of correspondents are not for obvious reasons preserved, but this one escaped destruction. At the time it was written our correspondent was strong and well with a promising future before him, and there was then no thought that his career would terminate so soon. The letter will not be the less interesting, inasmuch as its publication was not contemplated; it was simply a private letter, spontaneously penned, and, like other long private letters, would only be glanced at at the time of its arrival, hence was put aside for after perusal. Concisely is the sketch of our friend's life given. Vividly is his character portrayed. His life of labour, his thirsting for knowledge, his striving efforts at self-improvement, his untiring searching for truth, his perseverance, his determination to excel, all are visible. And what a lesson such a life is to young men. We know many of these are worthily striving, and glad shall we be if one can be found able to take up his "begun work," and continue it as he, had he been spared, would have continued it himself. In the letter which we now insert will be found the secret of his competency—constantly and unremittingly acquiring and storing knowledge; in it will also be found the origin of his once familiar and not soon-to-be-forgotten pseudonym "SINGLE-HANDED."

31st October, 1881.

SIR,—I promised in my last to acquaint you with some of the main points in my history, and I now take the opportunity of putting the same on paper. I was born at Ballo-Mill, Ladybank, Fifeshire, in April, 1851. My forefathers had been settled there for a century or two. I am, through my mother, descended from Andrew Melville, who gave Scotland Presbyterianism—the same man who, in a passion, informed James VI. that he "was God's ain silly vassal." In my youth—I left school at twelve—I spent two years with my uncle at railway-making, and learned some useful lessons, which have been of great benefit to me on more than one occasion. It was at this time that I acquired a taste for reading, and used to save my pence to buy papers.

At seventeen I went to Ramornie Gardens, the seat of F. L. Maitland-Heriot, Esq., lately deceased, to learn to be a gardener. The "youngest" and at once the oldest 'prentice I was frightened at being so long in going to the "profession," and did myself some physical injury in my eagerness to make up for lost time. All the gardening books I could get—such as "Mackintosh's Book of the Garden," Loudon's "Encyclopædia," Nicol's works, and half a dozen volumes of the "Scottish Gardener," were intensely studied. I became impressed with the idea that no one could be an accomplished gardener who was not well up in botany, geology, and chemistry. The cheapest way of securing works on these subjects was by buying "Cassell's Popular Educator." This I studied so intently that the doctor had to be sent for. Mr. Heriot lent me Balfour's "Elements" and "Class Books of Botany," Macgillivray's "Manual of Geology," Hugh Miller's works, Bence Jones and Miller's "Chemistry," and Liebig's "Agricultural Chemistry," with many others were also read attentively and studied closely while an apprentice. Ramornie was then a good old country garden. The collection of hardy fruit trees was as complete as nearly could be, and the gardener was one of the olden times, who went in for perfection in training, while all other branches of gardening were well conducted. The notes I took then I found of much value afterwards. When I left, which I did at the end of three years, I carried with me very flattering testimonials.

I then went to Delvine Castle, Dunkeld, the seat of Sir Alexander Muir-Mackenzie, Bart., at the Martinmas term, and was soon promoted to be inside

foreman. From thence I went to Kerse House, Falkirk, one of the seats of the Earl of Zetland, and served under a first-rate gardener; but after a year was tempted to leave to lay out a new garden on a somewhat extensive scale. Only a little was done, however; in fact, I was "sold." Another gentleman then advertising for a gardener "accustomed to glass," I applied, was shown plans for a good range of plant and some fruit houses, and engaged. The work commenced and good progress made in two years, also in taking in ground and planting. "Calculating" chances—and they looked good—I married; but just as we were preparing to finish the ranges of glass comes the City of Glasgow Bank smash, and everything was stopped. My employer always met his calls, but the calamity spoiled the garden. For my own credit I worked often much too hard, sometimes nearly breaking down, as I was left practically "Single-handed." Only by very hard labour could the place be kept well, and anything short of "well" is a misery to me. We have a small collection of Orchids, which I would be proud to place alongside of any other their own age in the country; also a useful collection of Ferns and stove and greenhouse plants. I have raised several hybrid Cypripediums and Dracænas, and other plants. Potatoes I have raised in hundreds, and have some good seedlings, also superior strains of different vegetables. Hardy Primulas and Auriculas I have sought to improve, and for everyday wear and tear commend me to good strains even of florists' flowers from seed instead of from cuttings. Only the hardier fruits thrive here, we are so exposed; but I would like to match the Grapes I grow for quantity and quality against the best and the heaviest crop ever seen.

During all the years I have unwaveringly sought to acquire knowledge, and have studied all sorts of books. I have a passion for the study of animal and vegetable physiology and organic chemistry, and with poetry I am entranced and general literature. In six years I have bought fully £45 worth of books, mostly gardening, but science generally as well. I possess or have read most of Darwin's works, Burbidge's, Johnston's, Church's, and others too numerous to mention. This off 27s. a week; but I have gained some prize money at shows, and Mr. Thomson's and your own kindness in placing me on your staffs has helped much. A little money gained thus is of much assistance to one who is endeavouring hard—

"To grasp the skirts of happy chance,
And battle with his evil star."

I have sometimes, when fate has seemed against me, felt cast down, but have never once "abated one jot of heart or hope;" but when failing to gain "reinforcement from hope" have taken "resolution from despair."

Till lately I have not endeavoured to gain another situation, hoping that things here would improve. My master is very kind, and we are on the best of terms; but under the present circumstances I think I should not slave hopelessly on, and, though it will be a trial to leave my work behind to begin afresh, I have made up my mind to do so. I should very much like to try my fortune further south in a better climate. To my calling I am devoted, and I ought to be well qualified to fill most situations. In fact, though that is "blowing my horn," the birthright of "every Scotchman born," I think not many have given greater amount of study to their profession.

I do not know whether it will count for much in England, but I am a ten-year-old total abstainer, and a life anti-tobacconist. My connection with teetotal societies has been of benefit, besides that derived from temperance, for I have been trotted out as essayist and lecturer at all sorts of times and occasions. In this I hope I have done good, though it does not bear on gardening.

Such are the outlines of my career hitherto—a career only fairly begun I hope, as I am but thirty. They are the merest outlines, but more is scarcely necessary, as you have some chance of judging details from what I write otherwise. Before closing I ought to thank you for the interest you have shown in me, and to assure you that while life lasts I shall never fail to feel grateful for your kindness; and should you ever favour me with a visit I shall reckon it a great honour.—ALEXANDER HONEYMAN.

Shortly after receiving that letter we had the opportunity of visiting Mr. Honeyman and inspecting the garden in his charge. The wonderful crop of fine Grapes, vigorously grown Orchids, and other plants under glass, with the superior condition of the outdoor crops, afforded ample evidence of masterly care, and of hard labour also on the part of the cultivator. It was this too-hard work that it is to be feared led to the illness that followed, and which was expected to terminate fatally at the time. The best treatment in the Royal Infirmary, Edinburgh, however, led to steady improvement, which it was thought and hoped would end in complete recovery. As Mr. Honeyman had decided to relinquish his charge, he resigned his situation during the early period of his illness, not deeming it right under the circumstances to receive wages when ill from a kind employer whom he intended leaving when well. He was not friendless during the long period of his convalescence, nor was he indulgent then. So much in earnest, and with a burning desire to impart and acquire knowledge, he could scarcely take the needed rest. When he could not lift the spade he could wield the pen, and we should not be surprised to learn that many of his best articles were written on a bed of sickness.

In October last, having regained much of his lost strength, he had a choice of situations, and decided to undertake a charge at Brighton, where, without having to engage in hard manual labour, scope for the exercise of his abilities would have been afforded him both in Grape-growing and ornamental gardening, while the recognised salubrity of the climate was not overlooked. As has been previously stated, after inspecting the estate that was placed in his keeping and estimating its resources he requested to be suspended for a short time, long and exhausting journeys having rendered, as he felt, a little rest needful. The sad result we know. After many weeks of suffering he died. He had looked forward confidently to success in his charge, and could see a wide field of usefulness before him, but eventually, and for some weeks prior to the end, resigned himself composedly and even cheerfully to the last sum-

mons, his one regret being, as he has stated, the helpless condition of his family. Though in a strange place it is gratifying to know that kind friends ministered to his wants, Mr. Coxed the Secretary of the estate, with his wife, and Mr. Amory the Clerk of the Works, having been untiring in their attentions by day and night, and their names are recorded here in appreciation of their valued services; his employers, too, we are glad to be able to state, kindly and considerably defrayed the expenses of the funeral. The remains of Mr. Honeyman were interred on Thursday last in a befitting manner, the coffin being covered with flowers—beautiful wreaths, crosses, baskets, and bouquets, the offerings of friends from far and near, and was lowered into the grave, in accordance with tender Scottish sentiment, by friendly, not hired hands.

Testimony of the appreciation in which our coadjutor was held is so

aware of is so advanced and so sound as was the subject of this notice. His writings have been closely examined by the highest authorities, and the author of them won the respect of the most learned, while he enjoyed to a remarkable extent the confidence of all students of garden literature. He was a writer in "Chambers' Journal," which is sufficient evidence of his literary ability; and just before his death he received an award of £3 3s. for the second-prize essay on "The Value of Rye Grass as a Herbage and Forage Plant, and its Suitability or otherwise for Sowing by itself or along with other Grasses and Clovers for Cutting and Grazing Purposes," offered by the Scottish Seed and Nursery Trade Association.

The measure of Mr. Honeyman's ability as a writer cannot, however, be adequately determined by what has been published. The MSS he

Fig. 29.—MR. ALEXANDER HONEYMAN.

voluminous that we cannot even cite in the briefest manner from the letters, all of which will be sent to Mrs. Honeyman. One, as typical of the whole, we insert, selecting it because the writer of it has the honour of first introducing Mr. Honeyman to the public as a teacher in scientific and practical horticulture.

"I am sure," writes Mr. D. Thomson, "your readers and all who knew Mr. Honeyman will much regret his loss and sympathise with his widow and children. It has been my happiness to be connected with him as a horticultural writer for 'The Gardener' for many years, and I always considered him the most advanced student in chemistry as applied to horticulture of any practical gardener of the present time, and it is to be regretted that he has been called hence at a time when greater opportunities of practice seemed within his reach."

Unreservedly do we concur in the above estimate. Not a few gardeners have considerable scientific attainments, but not one that we are

has left behind show the remarkable character of the man. Essays on almost every conceivable social and educational subject of current interest we have the mournful pleasure of inspecting; and he also found pleasure, as a relief from heavier subjects, in the composition of poetry. These manuscripts reflect alike the cultured mind and the extraordinary industry of one whom, as a gardener, one of the best of gardeners has remarked of him, "we shall not soon look upon his like again."

SHOW AND FANCY PELARGONIUMS.

It is a matter of opinion whether spring-struck one-year-old plants or old cut-back specimens of the Pelargonium are preferable. Young plants have many points in their favour, as they strike early and late; and by regulating their pinching and potting can be had in bloom from early spring until autumn. This can be also done with old cut-back plants

but not to the same advantage, neither is their foliage so good in appearance. Nevertheless, plants one year old cannot be grown to the size of old cut-backs, especially those of twenty or thirty years standing, neither are they so floriferous, and they require much more attention. Still, for conservatory work, with large staging and beds, I would grow both the old plants for the back rows and the others for the front.

When the flowering period of old plants is over stand them on a bed of ashes, fully exposed to sun and wind, to mature their wood. Give them little or no water, and should there be heavy rains lay them on their sides. Cut them back in August or September, and cut the old prunings to 2 or 3 inches long, and insert them after the manner of Rose cuttings, only in a frame instead of outside. Stand the plants in a cold frame, and as they become dry sprinkle them with a rose. When they have made an inch or two of growth shake them out, shorten the longest roots, and repot in a smaller size. Shake the plants when putting in the soil to cause it to settle amongst the roots. Many plants are ruined by omitting this process and allowing the roots to be massed in the centre. The compost should consist of two parts of good yellow fibry loam, half part well-decayed cow dung, half part leaf soil, and sufficient silver sand to make it porous. When potted place them in a good dry cold frame near to the glass. Water very sparingly, and with a rose. Do not damp the foliage. Close the lights, only give sufficient air to keep a dry atmosphere. In October the plants should be removed to a stage in a greenhouse or earlyinery, as if left out too long they will become affected with the spot, and many of the weaker varieties will be seriously injured, and some killed. Ventilation should be given at this period of the year to keep them robust.

To have them in flower early the most forward should be potted into their largest pots by the end of October, and for a succession of batches a fortnight later than the preceding one. If possible all should be in their largest pots by the end of November. Those that are left over should be potted in February and March, which time those potted in the autumn and encouraged to make all the growth possible and rested during December and January, can be receiving a liberal supply of liquid manure, that from the stable pump preferred, one pint to three of clear water, and syringe twice a day till the blooms open. To show old cut-backs to advantage every shoot should be staked. Hazel twigs are the best adapted to this purpose, or where they are scarce prunings from Pear and Apple trees will be plentiful, and are very good.

Cuttings for making one-year-old plants should be inserted in February, March, and April in a finely sifted compost of loam, leaf soil, and sand. When rooted pot them, and as the summer advances transfer them to a good light frame. They will require about two shifts, the same compost being used as before. Pay great attention to the pinching to get plenty of breaks, and a little liquid manure may be given.

The presence of green fly will be most injurious to them, and should be kept down by slight fumigating. Syringe twice a day, and close early, even if it is necessary to again open the ventilators and leave them open all night. Transfer the plants to the house with the old cut-backs, and treat them the same, except in the pinching, which must be regulated to induce them to flower late.—A FOREMAN.

RUBUS ROSÆFOLIUS CORONARIUS.

THIS is a free-growing and free-flowering plant of the easiest culture. Its growths are erect, but as there is a difference in the length of the shoots that spring each year from the base or stool it forms a compact plant of somewhat rounded pyramidal shape, and well furnished with growths to the base. The foliage is ample, and as fresh growths accompany the flowers it is attractive from its lively green colour, the old leaves having become somewhat sere ere the flowers are produced. It flowers from the points of the shoots, and every axil of the leaves on the stem down to very near the base pushes a growth, which is terminated by a flower, the plant when well grown being close-jointed. The flowers are elegantly formed, pure white and double, but with a notable eye, yet not detracting from its decorative value, and are about 2 inches across. It flowers more or less throughout the year, but is at its best during the early spring months when in a greenhouse. It can, however, be readily forced, and may be had in flower from early winter by having relays of plants introduced at intervals. Altogether it is a very elegant plant for the greenhouse, having the aspect of a small-growing Bramble with leaves similar to a Rose.

It may be grown and flowered in 6-inch pots if well fed with liquid manure during the season of growth; but to see it in character it requires more root room, the size of the pots being as a matter of course regulated according to the size of the root-formation, as, for instance, a plant that flowered this year in a 6-inch pot will need a pot 3 or 4 inches larger in the next, and so on each year until very fine specimens can be had in the second and third year, when they are as large as need be for ordinary purposes, and by reducing the ball at potting time the plants can be kept in the same size pot for any length of time. Its growths are annual—made one season and flower the next, so that the old shoots should be cut out after the plant has flowered, not being in too great a hurry, however, as there is reason to believe that the old growths feed the young ones that spring from the base for at least a time.

The best time to repot this plant is as soon as the flowering is

over and young growths are appearing. The old soil should be picked from the sides of the ball, reducing it somewhat, but not to a greater extent than a third, returning the plant to the same size of pot or a little larger, and when it has rooted freely transfer to the flowering pot; or instead of this it may be well fed when in free growth. Good turfy loam, with a fifth of old thoroughly decayed manure and a little sand will grow it well, good drainage being given, as it is a plant that requires copious supplies of water. No stopping, training, staking, or tying is necessary. It is a native of the Himalayas, Burmah, &c., and though not new was but little known until brought out by Messrs. Veitch. As a decorative plant and for cutting from it deserves extended culture. Propagation is effected by suckers or cuttings of the shoots that spring from the base after they become a little firm.—G. ABBEY.

HARDY PLANTS AND THEIR SYNONYMS.

I QUITE agree with "Specialist" that great confusion exists regarding the names of hardy plants, and if some of the correspondents of the Journal would give a few names of plants occasionally with their more popular synonyms, such, I am sure, would be greatly welcomed by many a reader of the Journal, which I am pleased to see is giving us so much useful information on hardy herbaceous plants. Great advantages accrue from being made familiar with the synonyms of plants, as it very often prevents us making unnecessary purchases, and subsequent disappointment. Suppose I make a speciality of Phloxes. *P. reptans*, like many others, does well with me, and the fact of this is great inducement to add other species to my already good and flourishing collection. In looking over my catalogues I meet with the name of one apparently new to me—namely, *Phlox stolonifera*. I purchase a plant, which on its arrival proves, to my great surprise, identical with my *P. reptans*. These unlooked-for disappointments can best be diminished by making ourselves better acquainted with plant nomenclature, and much credit is due to "Specialist" for so boldly setting us the example. I will volunteer my mite towards supplementing the list given by him, but before doing so allow me to draw attention to a few errors in "Specialist's" list. For instance, how can *Achillea serrata* be confounded with *Achillea Ptarmica*, or *Campanula lamifolia* with *C. alliariaefolia*? I regard them as species very remote from each other. *Androsace septentrionalis* we must regard as a well-marked species very distinct from *A. lactiflora*, which latter is synonymous with *A. coronopifolia* (Andr.), the name generally kept up, and under which it is figured and described in the "Botanical Magazine."—PRACTICAL.

I HAVE read with much interest the articles on "Synonyms of Hardy Plants" in your valuable Journal, and I remarked in your last number that your correspondent finds *Campanula fragilis alba* a difficult plant to grow. I have a starry white *Campanula*, purchased under the name of *C. isophylla alba*, which, if not the same, is extremely similar to *C. fragilis alba*, and a most valuable plant for hanging baskets in a conservatory. I find it increase freely in a damp place out of doors, and the main stock will do well grown so and potted as required.—L. B.

ELECTION OF CARNATIONS AND PICOTEEES.

THE ELECTORS' RETURNS.

[The names of the raisers of the varieties in the following lists have been given in the previous returns.]

THE VINE.

THERE is no subject among those which engross the gardener's attention of more importance than the cultivation of the Vine. No garden appears fully furnished without its vinery for its cultivation, and no table, however loaded with dessert, is perfect without the all-important Grape.

No one can fix the country where the Vine is indigenous, but the history of all nations prove that it has been one of the earliest cultivated fruits, and that is not surprising, seeing that it is one of the most delicious in its fresh state, and makes a very good dessert when it is dried, while the different kinds of wine manufactured from its juices prove it to be the ne plus ultra of fruits in excellence and variety of uses, and there are thousands of witnesses who can testify to its value in the sick chamber.

The propagation of this queen of fruits is effected by means of seeds cuttings, layers, and grafts. Propagation by seeds is mainly with a view to obtaining new varieties, which is done by crossing different varieties which have been obtained previously by that means or by accident. The seeds should be sown early in February in pans of light rich loam mixed with a little leaf soil. The pans should be placed in bottom heat, and the seedlings potted as soon as necessary, plunging them in bottom heat, and keeping them there through the growing period with plenty of light and ventilation when they require it, and under favourable circumstances they will bear fruit in three or four years.

Propagation by cuttings is effected by taking pieces of well-ripened wood 9 or 10 inches long, or by single eyes, which is preferable, and the mode most approved of by all good cultivators affording better rooted plants and strong short-jointed and well-ripened wood. The eyes are best that are taken from the strong healthy Vines, cutting them, say, an inch above and an inch below the eye, making the cutting 2 inches long. They should be inserted singly in pots 4 or 5 inches in diameter in good rich mellow loam, well drained, and the buds placed in about an inch in depth; the pots must then be plunged in bottom heat of from 70° to 80°, and an air temperature of from 60° to 70°. The cuttings should be shifted when they attain the height of 7 or 8 inches into 7 or 8-inch pots, and again plunged. The best compost to put them in is good fibry loam, with a small quantity of leaf soil and manure, and a piece of charcoal and sand added to it, taking care that the pots are well drained, and if the roots appear above the surface of the soil the plants may be placed in 12-inch pots. Propagation by layers is very little resorted to now, and I think that cuttings or eyes are very much superior.

Propagation by grafting is seldom employed, except for the purpose of superseding a sort that is not required by one it is wished to have in its place, and to fruit quickly; also if it is desired to test a new promising variety it can be sooner done by grafting. Vines may be successfully cultivated in the south against walls. The soil should be well drained; a mellow sandy loam is the best, but an ordinary friable soil will answer, provided it is well drained, but seeing that glass is so cheap there is much more inducement to cultivate them under glass than formerly.

Vines grown under glass should have their borders made very carefully and one of the most essential things is to have the borders well drained. The border should have a bottom of from 6 to 12 inches of rubble or brickbats, with a good outlet, and for a drain for the water, upon that a layer of turf should be placed, then a compost may be made of the following proportions:—One-half of good fibry loam or turf rather sandy, a fourth part of good coarse manure, and a fourth part of coarse bone manure, rough or lumpy charcoal, and old lime or plaster from buildings. This should be well mixed and a layer of about 18 inches placed on the top of the turf, then the roots of the Vines should be laid carefully on this, and a layer of 6 inches placed over the roots. The border made be made from 12 to 20 feet wide, according to circumstances, but some make the borders narrow, and after the Vines have been growing for two or three years add another width to it. The above directions will apply to those grown in a stove, with the exception that the border should always be inside, so that the temperature of the roots and branches may be as uniform as possible.

Planting.—Vines are best planted just before the buds commence swelling, but some recommend that they should be grown for a few inches before planting; but this only applies to those that are in pots, as it would be against reason to do so with those that are to be taken up and transplanted. In planting care should be taken that the roots are not injured in the operation, and if the roots are unavoidably injured, as is often the case in shifting good-sized Vines, the roots so injured should be pruned with a sharp knife to avoid any canker that might ensue.

Pruning and Training.—Vines bear their fruit on wood made in the current year. There are three systems of pruning and training Vines—viz., the long-rod short-rod, and spur; but whichever system is adopted, the chief consideration should be to get the greatest amount of foliage exposed to the light, as overcrowding is detrimental to the ripening of the wood and fruit.

Long Rod System.—Larger bunches, it is admitted, are produced by the long-rod system, but a larger quantity and greater weight are produced by the spur system. The Vines should be planted about 4 feet apart for general purposes, and after the Vine has grown one season it should be pruned back to the bottom of the rafters. The following season two of

the best shoots should be trained, and when they have completed their growth cut one of them back to two eyes, and the other should be pruned to a convenient length for producing fruit; while the other, which was cut back to two eyes, will produce two shoots that will have to be pruned in the same way—that is, one of them left and the other cut back to two eyes again. There will thus be a succession of fruit-bearing wood, while the shoot that has borne the fruit the preceding season should be cut out. If, however, the Vines are wanted to cover more space, they must be trained so that there shall be two or more sets to bear fruit like the above.

The Short Rod System.—This is on the same principle, but buds should be selected alternately from each side of the shoot. The others being removed from between the chosen buds, they should be disbudded when the wood is nearly ripe. The buds that are left generally bear the following season. The shoots produced from the buds that are left are stopped in summer to one eye beyond the fruit, and in autumn are pruned to two eyes. One of the shoots produced from the two eyes is allowed to bear fruit while the other is not. In autumn again the shoot which bore fruit is pruned to one eye, while the other is pruned to three or four eyes, so that there may be a strong bud left at the end to produce the fruit next season. The other buds, with the exception of that at the base, are taken off; two buds left, one at the apex and the other at the base, one to bear fruit and the other to form the succession shoot the following season, while the bud left on the base of the other shoot forms the fruit-bearing wood for the season after.

The Spur System.—Spurring has become the general way of pruning Vines. They should be planted so that each Vine is grown in the centre of a sash or light, for if they are planted as they often are and trained up a rafter, they will not get the light they require. Great care should be taken in pruning Vines in this way (namely, to two or three eyes) to get their shoots to push alternately by the removal of every other bud, and two might very safely be removed in very short-jointed wood. As soon as the young shoots have pushed so that they can be tied in, they should be stopped at one joint beyond the bunch just showing, or where there is plenty of room they may be stopped at two joints beyond the fruit, but a gardener in this case, as well as many others, must use his own discretion. After this laterals will push, and these should be stopped above their first joints, and so on through the entire season.

Thinning.—When a Vine has more bunches than it is thought can be perfected—and here a gardener has to use his judgment—they should be thinned, care being taken that the worst bunches are taken off, and that the bunches left are at regular distances apart. There is no prettier sight than a house hung with ripe bunches, as if the distances had been measured. The sooner those that have to be sacrificed for the good of the others are taken the better—that is, as soon as it can be seen what the bunches are going to make. If a gardener is greedy he is deservedly punished by the unsatisfactory results that follow. The berries should be thinned as soon as they attain the size of small peas, care being taken that those nearest the centre of the bunch are taken first. In thinning a bunch the operation should be commenced at the end, working upwards towards the top of the bunch. Some bunches are cone-shaped, while others form very distinct shoulders; these should be tied up, taking out all the berries that might become overcrowded, and in all cases care should be taken not to touch the bunches with the head or hands. The bunches should be examined again in a short time, and those berries that show the least signs of being overcrowded should be taken out, and the old maxim of quality before quantity should be the guide.

Temperature.—Vines should be started with a temperature of from 40° to 45° at night and about 50° by day, increasing to 60° with sun heat, the heat being gradually increased (while the buds are swelling till they are in leaf) up to 55° at night and from 65° to 70° by day up to 75° with sun heat. When the Vines are flowering the temperature may be increased to 65° at night, 70° by day, and 80° with sun heat. Muscats require a rather higher temperature—say 70° at night and 80° to 85° by day. Great care must be taken in regulating the temperature of vineries that there is not a sudden influx of cold air. Ventilation should be given to keep the house at such a temperature rather than to lower it when it has become too high by neglect; but practice alone makes a man perfect in ventilation, as in all other things.

Diseases.—Shrivelling is a disease that is owing to the roots of the Vine not supplying a sufficiency of sap, which is caused by their being in too low a temperature. This often occurs in stoves where the Vines have their roots in an outside border, the temperature of the border being considerably less than that inside; or it may be caused by the roots getting into some substance that does not suit them, and if their roots were examined it would be found that the fibre was very much discoloured, and in some instances quite decayed. We sometimes find bunches that have from three to ten berries quite colourless and sour, while the others have both colour, and this is also caused by the great difference in the temperature of the roots and the Vine.

Shanking is also caused by the same mismanagement—indeed, most of the diseases that the bunch is subject to is caused by the carelessness or mismanagement of the gardener, or in some instances ignorance.

Rust is supposed to be caused by overheating the vinery, and then as suddenly reducing it, which should by all means be avoided.

Spot on Grapes is caused by changes of temperature, irregular watering, and growing the Vines in too low a temperature. This disease often occurs in the case of Muscats, which proves that it must generally be caused by too low a temperature, seeing that the Muscat is most likely to suffer from want of heat. Want of colour is caused by the Vine having too heavy a crop or having an insufficiency of foliage to elaborate the sap, or it may be caused by the bunches being too much exposed to the solar

rays, and becoming by that means partly burnt in order to secure the good colouring of Grapes. Care should be taken not to hurry the ripening process, as we often see perfectly coloured Grapes grown without any artificial heat at all in the north of England with the simple protection of glass, and then often subject to ventilation both night and day, and in the south those grown against walls are often a beautiful colour.

Mildew is a disease that often attacks Vines, but which can be checked by the application of sulphur in the form of vapour, also by mixing it with the paint that is used to paint them with in their dormant state.

Insect Pests.—Red spider is one of the pests that often infest Vines that can be destroyed by the application of sulphur in the form of vapour. Also the frequent use of the syringe is beneficial in checking it, as a hot dry atmosphere is favourable to its increase. Thrip is another pest that infests the Vine, but a good fumigating occasionally will effectually keep it in check.

Scale and mealy bug sometimes attack the Vine. When this is the case cleaning off all the loose bark and washing them in warm water mixed with soft soap is a good cure; also washing the walls or painting them with a mixture of lime, sulphur, and tobacco juice. If the vineries were kept clean and frequent syringing there would be less to contend with than is often the case.

Bleeding of the Vine is caused by the Vines being pruned after the sap has commenced rising. This can be avoided by pruning them as soon as the leaves have fallen; but if by chance they should be left too long and they bleed at all, that portion might be seared with a red-hot iron, or the end might be thrust into an entire potato, which is as good a preventive as I know.

Varieties of Vines.—The following are a few of the best varieties for a greenhouse or vinery:—Black Hamburg, Black Prince, Lady Downe's, West's St. Peter's, Royal Muscadine, Dutch Sweetwater, Trentham Black, Gros Guillaume. For the stove the following are very good:—Muscat of Alexandria, Canon Hall Muscat, Black Hamburg, Bowood Muscat, Muscat Hamburg, and Gros Guillaume. The above are varieties that have been grown by myself, and for general purposes are among the best varieties that can be cultivated.

No man now ought to be long ignorant of any subject in gardening, seeing there are so many valuable works and periodicals on the subject that he may want information on, and if he begrudges the few shillings or pence that these works cost he cannot have that interest in gardening that he ought to have, and which is indispensable in the making of a good gardener—JAMES INMAN, *Chapel Ailerton*.

[The second prize paper read at the Leeds Gardeners' meeting.]

PASSIFLORA EDULIS.

To the request of a Kentish correspondent ("Super"), who desires to know "all about *Passiflora edulis*, its culture, and its uses," we cite the following from a previous issue, as such a comprehensive question cannot be answered satisfactorily either to our correspondent or others in the form of a brief reply in the column devoted to inquiries.

THIS is an interesting species of an extensive and beautiful family of climbing plants. Most of them require a stove temperature to bring them to perfection, although *P. carulea* and its varieties will flourish on a south wall in the open air in the southern counties. But *P. edulis* while being a native of India will still succeed in a lower temperature than many of its allies—that is, it will cover a roof and flower freely in a warm conservatory, yet to perfect its fruit it requires, and is worthy of, stove temperature. Its flowers are not nearly so beautiful as those of some other varieties, but its handsome plum-like fruits, which are so easily and freely produced, add an interest to the plant to which its more gay compeers can have no claim. The fruit, besides being decidedly ornamental, has a flavour which is particularly agreeable to some palates; and where such is the case, and means are provided, it is specially grown for dessert purposes. In the gardens of Drumlanrig Castle a house is solely devoted to the culture of this fruit, and large crops are produced. The fruit has a pleasant aroma, is cooling, and has a refreshing subacid taste, and is particularly adapted for allaying thirst in the tropical countries to which it is indigenous.

As an ornamental roof-covering plant it is to be feared that *P. edulis* has frequently given place to less worthy objects. It is not easy to find a plant more beautiful than this with its elegant pendant shoots laden with flowers and fruit, which hang with an airy gracefulness from the roof of a suitable glass structure. The plant is, moreover, of very easy culture. It should be raised from cuttings in preference to seed. Seedling plants grow freely enough, and soon cover a large space, but they are sparse in blooming compared with plants which have been struck from cuttings. Short-jointed young shoots strike quite easily any time during the summer if put in sand under a bellglass, and attended to by the requisite amount of heat, shade, and moisture.

A suitable compost for established plants is turfy loam two-thirds, the remainder leaf mould, peat, and old decayed cowdung, this to be liberally mixed with sand and broken charcoal. Although the plants require an abundant supply of water during the summer season any approach to stagnancy is pernicious, and consequently the drainage must be very complete. It is well, too, in potting to place some crocks or rubble round the neck of the plant, as it is apt to canker and decay at the surface of the soil; but to grow it well it should be planted out. Corners of bark pits, walled-off from the bottom, form fitting receptacles in which to plant. In these, with due attention, plants will flourish for many years. In the summer season a free use of the syringe is necessary, as a dry atmosphere, and especially if dry at the roots, if only occa-

sionally, at the same time, will certainly invite a crop of red spider. Syringing must be less frequent pending the setting of the fruit, which is aided by each bloom being artificially fertilised with its own pollen. On this point the same treatment that is given to Vines is applicable.

In the winter the roots must be kept somewhat dry, yet even then the soil must always be perceptibly moist. A minimum winter temperature of 45° is safe, and a plant that has been preserved for some years at a lower temperature than this, but it is not advisable.

In training, a vital point is to guard against overcrowding. If the young shoots are suffered to cling together and become interlaced, the plant will lose vigour and only produce useless spray. The aim should be to have the young growth thinly disposed, so that each shoot can have the benefit of light and air and become matured. It is only by this means that fruit can be expected. Spring is the best time for pruning, just when the plant is commencing to grow. The shoots can then be thinned out and shortened, so as to cover the space required. Taking out

Fig. 30.—*Passiflora edulis*.

old wood by degrees and laying-in young is the necessary mode of prolonging the vigour of the plant, and to preserve it in a flowering and fruiting state for many years.—W.

HOLLIES.—The salt winds have been blamed for defoliating Hollies all over England, caused by the December storm. I think a little more information is desirable. I would suggest that the salt had nothing to do with the leaves falling, but that the terrible force of the wind ruptured the leafstalks, and the active state of the roots assisted by the open and mild winter caused the old leaves to fall and give place to a new growth.—J. E. WAITING, *Grange-over-Sands*.

HARDY FRUIT GARDEN.

Arrears of Work.—Buds of Nectarines, Peaches, and Apricots are becoming very prominent; many Pear buds have swollen almost to bursting, some of the Gooseberry bushes are dangerously forward; it is high time, therefore, that winter work should be finished. In well-managed fruit gardens the pruning is all done excepting amongst the Filberts and Nuts, which will quickly follow, for the pink brush-like female flowers are fast opening, and many of the catkins, or male blossoms, have some pollen, and when this becomes so plentiful that the

fertilisation of the female blossom is a certainty pruning may be done. Planting is over; all newly planted trees are securely fastened to wall, espalier, or stake, are labelled, and mulched with manure. The entire plantation of Gooseberries, Currants, Raspberries, and Blackberries has had a thick surface dressing of old hotbed manure, the nailing and tying of wall trees and espaliers is done, wood for grafting old exhausted trees or inferior sorts has been thrust well into the soil at the foot of a north wall, screens, netting, and mats, are at hand for the protection of the blossom, and all is in readiness for the coming of spring. We thus briefly enumerate the chief details of our winter work as a reminder to all still having arrears on hand to delay no longer the finishing of work that cannot be put off without considerable risk of harm to the trees.

Our last planting was several rows of Red Warrington Gooseberry which we find one of the most useful sorts of this popular fruit. It invariably crops well, the green fruit is ready for picking early, the ripe fruit keeps good later than almost any other sort, it makes delicious rich-flavoured jam, and is one of our best dessert fruits. Its growth is sturdy and free, and the bushes continue healthy and in full bearing for many years; some planted thirteen years ago still show no signs of debility or decay. Fruit-growers for market find a plantation of this hardy prolific Gooseberry a profitable investment. The bushes are 5 feet apart, with a row of Strawberries between them for three or four years, especial care being taken when the Strawberry plants are destroyed to thoroughly enrich the soil they have grown in with manure for the benefit of the Gooseberries.

The Fruit Book.—Every fruit tree planted should have its name entered in the fruit book, and sufficient space left for subsequent entries of importance, such as when it first has fruit, freedom from or tendency to disease, root-pruning and its effects, an annual note of its condition and crop, the quality, size, and season of its fruit, and any special method of treatment, so as to gradually accumulate a fund of useful knowledge that cannot be obtained in any other way, for many of our best sorts of fruit are so much affected by local peculiarities of soil and climate that it is hardly possible to say if they will answer without actual trial. By keeping such a book for several years we are now able to plant with certainty, and to assist many of our neighbours who are planting in the selection of the best sorts of fruit for our locality.

FRUIT FORCING.

FIGS.—*Early Pot Trees.*—Continue the treatment advised in the last calendar, guarding against the evils which usually attend a high temperature, especially at night, until the days are longer and brighter, when by judicious treatment in early closing with plenty of sun heat and moisture anything now apparently lost will be regained by the increased vigour of the trees and rapid advancement of the fruit. Attend regularly to the wants of the roots, and guard against a check from an insufficiency of water by giving copious supplies of tepid liquid as frequently as may be considered necessary. In the case of old-established plants the rapid increase of the fleshy roots filling the space left for water, a rim of zinc or lead about 4 inches deep may be placed round the inside of the pots for the reception of rich mulching, and to prevent the escape of water when supplied in sufficient quantity, as it should be to penetrate the ball. Syringe twice a day in fine weather, and moisten the paths, bed, and walls only in dull weather or when the drying of the foliage before night-fall is doubtful. Stop gross shoots, a few at a time, following the extension system where space admits, removing a few of the badly placed fruits if thickly set.

Succession Houses.—Repeat the treatment described for early trees. Let the temperature range from 55° to 60° at night. Mulch and water freely as a means of keeping the roots near the surface, and so maintaining the fertility of the trees. There is a difference in the prolificness of the varieties, some being more so than others, but all succeed best under prescribed root space in good loam of a calcareous nature resting on clear drainage through which water can pass freely. Red spider is the most troublesome enemy of the Fig, and unless provision is made for the free use of water, keeping the tree clean and healthy is impossible.

Late Houses.—Complete the pruning of the trees in the latest houses. The shoots should be all thinned and laid in over a trellis 16 to 18 inches from the glass. When the bearing wood reaches the extremity of the trellis it should be cut away to make room for the most promising successional shoots, which produce an abundance of young fruit on ripe wood ready for development in the spring, and instead of keeping the autumn growths closely tied down they should be allowed to draw up to the glass to receive the full influence of the sun.

Cucumbers.—The weather so far has been very favourable for forcing. Continue to tie down the young growth, and thin out all superfluous shoots and badly formed fruits, syringing the plants in the afternoon of fine days, and keep the evaporation troughs filled with liquid manure, the ammonia from this being healthful to the plants and inimical to insect life. The bottom heat should be kept steady at between 80° and 90°, and liberal supplies of tepid liquid manure given whenever the plants require it.

Young plants must be well attended to, affording a minimum temperature of 70°, admitting a little air at 75°, keeping it through the day at 80° to 85°, closing at 85°, and then run up to 90°. Attend to the linings of dung-heated frames, which as soon as the heat begins to decline should be removed, and fresh sweetened material supplied from the reserve heap.

Melons.—The first plants are making good growth, and must be encouraged in every way, maintaining the bottom heat at 85° to 90°, and be careful not to overwater, and yet enough must be afforded to keep

the plants in free growth. A genial condition of the atmosphere must be maintained by sprinkling available surfaces—*i.e.*, the walls, paths, &c., and as they become dry, or in the morning and afternoon, and on bright days the plants may also be sprinkled in the morning and early afternoons. On bright mornings admit a little air at 75°, keep through the day at 80° to 85° from sun heat, closing at 85° and run up to 90°, maintaining a night temperature of 70°. Keep a sharp look-out for slugs. See that the linings of dung-heated Melon frames are attended to as they require it, which under ordinary circumstances will be about every ten days or a fortnight, varying of course with the weather and the condition of the materials when the bed is made up.

Strawberries in Pots.—The mild winter is now making itself conspicuous in the results, and the forward vegetation will need protection where it is at all practicable. Where large quantities of Strawberries are forced it becomes necessary, where frames are not available, to erect some sort of protection of a temporary character that will meet the likelihood of injury being done to the tender young growths from the frost or wind. It will therefore be advisable to have all plants that are showing growth collected together and protected from the effects of probable inclement weather. Those intended for a late supply will be best accommodated in pits and frames behind a north wall, for when kept in a favourable aspect for growth they are apt to start before they are required, and thereby interfere with the arrangement for succession. The whole stock should now be examined, the surface soil removed without interfering too much with the roots, and be top-dressed with short manure, which encourages surface roots, and the drainage being seen to and if defective rectified, a healthy condition of growth will result.

With an increase of light the temperature for plants that are swelling their fruit may be raised considerably, but it ought not for the present to exceed 85° at closing time, accompanied by plenty of moisture. Where a quantity of plants is forced and a constant succession must be kept up, it is imperative to set apart a house for the swelling-off of the crops, so that the plants that have fruited can be recruited from the ranks of plants in other houses in rotation.

PLANT HOUSES.

Zonal Pelargoniums.—Those plants that were placed in 5-inch and 6-inch pots in autumn, and have been wintered near to the glass in a temperature of 45° to 50° should now be dwarf and sturdy. These if placed in a house 5° or 10° higher at night will soon flower. Keep them dwarf and sturdy by the admission of air daily, and have the atmosphere in which they are placed rather dry. Water carefully, but as soon as the flower trusses are visible give weak stimulants every time they require water. A good number of dwarf plants may be selected for flowering again from amongst those that ceased flowering in autumn and early winter if they have been properly cared for since then to the present time. Those required to flower as early as possible should not be cut back or stopped, but placed close to the glass in a night temperature of 45°, and as soon as they show their flowers they may be treated as advised above. If in small pots they may be given a small shift as soon as they commence flowering, but we prefer feeding them. Another batch of dwarf plants may be partially cut back, and when they have commenced growth should have their roots reduced and placed in the same size pots. A good position to start them in after cutting back is a shelf in a vinery or Peach house. Do not give too much water until they break, but syringe occasionally. Those plants that have become tall and have been kept dry to harden their wood may now be pruned close back and placed in gentle heat until they break; when the atmosphere is not too moist, do not give much water, but syringe occasionally.

Young stock rooted in autumn and wintered in 2-inch and 3-inch pots on a shelf near to the glass in the greenhouse should now be placed in 4-inch and 5-inch pots. Give them a temperature of 50° until they commence rooting, and then grow them under cool conditions. If the stock has to be increased of either double or single varieties, cuttings inserted singly in small pots will now root readily on a shelf in a temperature of 60°.

Cinerarias.—These plants are in good condition this season, and the winter has suited them exactly, for they do not like fire heat, which often during severe winters, has to be employed to exclude frost. There is nothing that proves so injurious to these plants as fire heat, and it should always be avoided as much as possible. Fortunately very little has been needed, and therefore they should generally be in good condition. The mildness of the weather has brought them forward more rapidly than could have been wished, for many of the latest batch have commenced showing their flower stems, which are advancing rapidly. These may be removed to a cold frame, which should be ventilated as liberally as possible to keep them back, but be careful to place them where frost can be excluded. Feed liberally all plants that are coming into flower, and be careful that they do not suffer from an insufficient supply of water at their roots. Watch for aphides, and on its first appearance fumigate with tobacco smoke, or they will increase rapidly and soon spoil the plants and flowers.

Calceolarias.—The most forward plants are in good condition for placing into 6, 7, and 8-inch pots where large plants are required. The smaller plants may be repotted on as they require it, and will do much better in cold frames where frost can be excluded than what they will upon shelves or in large dry houses. These plants should never occupy such positions in any stage of development, for they delight to stand upon some moisture-holding material. Employ for a compost three parts of fibry loam, the other part being composed of leaf mould and prepared cow manure rubbed through a fine sieve, add sufficient sand to

make the whole porous, and a 5-inch potful of soot to each barrowful of soil. These plants are much subject to attacks of aphides, which on their appearance must be at once destroyed.

Lilium candidum.—Where these are grown in pots do not over-force them, or their flowers if produced will be small. When the flower stems are advanced about 18 inches remove them to a cool house or where the temperature is not higher than 45° at night; ventilate freely, and feed liberally as soon as the flowers are set. No Lily is superior to this for cultivation in pots for early flowering.

THE FLOWER GARDEN AND PLEASURE GROUND

Pruning Climbers.—The various hardy plants employed for covering the walls of dwelling houses and other similar positions are, when once their allotted space is covered, too often allowed to grow at random. Unless annually pruned and the main stems nailed or tied up, they soon become mere thickets of growth, and instead of being decorative are more often extremely unsightly.

Roses.—All such as are growing in sheltered positions, if pruned at once, will in all probability afford abundance of early blooms. Maréchal Niel and the Banksians require similar treatment, both flowering at nearly every joint throughout the strong growths formed during the previous summer. Thin out these growths and all spray in order to secure the requisite number of shoots for the following season's display, and neatly lay in the remainder, all the pruning these require being merely the removal of weakly or unripened points. Teas and Noisettes, including the popular Gloire de Dijon, should have strong leading growths laid in where required, weakly growth hard pruned to induce the formation of stronger flowering wood, and the remainder shortened back to three or four buds, or according to their vigour. Hybrid Perpetuals, Bourbon, and China Roses may be similarly treated.

Wistaria sinensis.—These are generally trained similarly to horizontal Pear trees. Where necessary, lay in the single leading growths, the unripened ends only being shortened, and spur back all the remaining strong lateral growths, this resulting in the formation of flowering spurs. They should not be crowded, and each main branch ought to be not less than 10 inches apart.

Chimonanthes fragrans.—The flowers of this deciduous shrub are borne principally on the spray, and to secure this lay in strong ripened shoots as much as possible, and these next season will produce flowers at every joint. Cut back all strong lateral growth directly after flowering, but not too severely, and this was also result in the formation of more spray.

Pyrus japonica and Crataegus Pyracantha.—Neither of these flower freely if allowed to grow into thickets, which the latter especially is apt to do. Any that are in this state should be cut hard back, and if the young shoots resulting are thinned out or laid in, these during the second spring following will have flowering spurs at every joint, and very beautiful they will prove, the Crataegus subsequently developing into wreaths of showy berries. Any not much crowded will yet be improved by being shortened back, and lay in the long shoots formed last summer wherever possible.

Jasminum nudiflorum and Forsythia viridissima.—Both these flower on the young shoots formed during the previous summer, and to secure abundance of these directly after the flowering period is past, cut the whole of the lateral growth hard back, only laying in any where space is yet to be covered. The Forsythia is the latest, and ought to be as common as the Jasmine. The common Jasmine (*J. officinale*), to be closely cut back to the main branches, the flowers being borne on the points of the many young shoots resulting.

Clematises.—The early-flowering sorts, such as Albert Victor, montana, Lord Londesborough, lanuginosa, and varieties produce their lovely flowers at nearly every joint of the strong growths formed during the previous season; these, therefore, should be merely thinned out where required, those reserved shortened where weakly, and neatly laid in. Those of the C. Jackmannii type, including rubro-violacea, rubella, tunbridgensis, Prince of Wales, and Alexandra, flower from the current year's growth, and to secure the requisite number of strong shoots freely thin out the old or last season's wood, and shorten back those reserved to within a few joints of their starting point.

Loniceras.—The Japanese and golden-variegated varieties should be freely cut in to the main branches and plenty of bloom will follow. Ivies also should have all loose growth cut hard back to the main stems, and any of the latter not firmly attached to the walls should be secured with shred and nails.

Magnolias.—The large evergreen sorts should merely have the long straggling shoots laid in and the fastenings to the main stems renewed where required, as strong winds have much power over these large-leaved shrubs. The deciduous varieties form short flowering spurs, and all that is necessary in their case is to cut back any strong lateral shoots. Ceanothuses also to be freely cut back, these flowering on the current year's growth. Passifloras to have all old flowering growths cut back to the main stems, and Fuchsias and Aloysia citriodora to be either cut down or spurred-in to the main growths.

Planting.—It is not yet too late to plant any of the plants mentioned, especially as the majority are supplied in pots. Form a good border, digging deeply and manuring freely, and well ram the soil about the balls of roots. Mulch with short manure or leaf soil, and never let them become dry at the roots.

CULTURE OF POINSETTIAS.—In answer to your correspondent, Mr. J. Sanderson, in the Journal of February 7th, page 105, I agree that they require a higher temperature where he is situated than they do in Sussex. The bracts on Mr. Sanderson's plants must be extremely

handsome, perhaps he may oblige the readers of this Journal with a few useful notes.—C. H. STEPHENS, JUN., *Lyne Gardens, Sussex.*

THE BEE-KEEPER.

FEEDING BEES.

MORE than one inquiry having reached us whether weak hives should be fed in the spring, we cannot do better than publish what has been written on the subject of feeding bees by the late Mr. John Hunter:—"The means by which food may be administered to bees is elsewhere considered, and I will now explain when and in what quantity it should be given. At the time a swarm issues the weather is generally fine; but it sometimes happens a change takes place, and the swarm having no stores, and not being able to gather any, of necessity suffers. Such a contingency happening, the prudent and merciful bee-keeper will give food at once, not too fast—say half a pint of syrup *per diem*; if a superfluity be given the swarm will occasionally construct drone combs to store it in, which is not desirable. Bees when they swarm seem filled with an uncontrollable impulse to build combs; this is a necessity of their future existence, and it is of the utmost importance that the impulse should be fostered and encouraged. The queen cannot of course lay an egg without a cell to put it in, and as she is capable at this time of laying 2000 or 3000 each day, the waste to their owners will be easily seen should all these embryo bees be lost. Old stocks in the spring have their stores at the lowest ebb; the winter's consumption has not been made good, and unless the prudent insects find food is coming into the hive no great amount of breeding will take place. Of course the earlier bees breed the sooner they will swarm or store in supers; and in a great measure breeding may be induced at the will of the bee-master. As soon as the weather will allow in the spring every stock should be examined, and if found deficient in food it must be administered. In cold damp weather too much syrup is not good; there is no objection to sufficient being given for daily consumption, but the bees must not have enough given to fill their combs, or the damp arising from it will very likely cause dysentery, and if over-supplied they will be apt to store it in the centre combs, being the nearest, and these are all just which should be left for the queen's use. Barleysugar is a very good food for such times, and may be given to the bees either in a bottle or put into the hive, not too much at a time, or it may liquify and form a trouble as well as waste. Barleysugar, superior to that bought at confectioners, may be made as follows, viz.:—

"Break up 3 lbs. of loaf sugar, place it in a saucepan or preserving pan, and pour half a pint of cold water upon it and half a wineglassful of vinegar, these are all the ingredients required. Prepare a fire in a grate, the top bar of which will let down in a similar way to that in an ordinary kitchen grate, taking care, however, that at the commencement of the operation the bar is up in its place, and the grate full to the top with glowing cinders or wood embers, so that a great heat may be obtained without any flame. The saucepan containing the sugar place upon the fire and stir it without ceasing. In a few minutes it will begin to assume the character of dirty broth, which will have anything but a nice appearance, but presently a thick scum will rise and the mass will try to boil over. As soon as this is observed the saucepan should be removed from the fire until the ingredients have cooled a little, when it should be set on the grate again in such a way that only a small part of it is over the fire; the boiling will then go on on the exposed side, and as the ebullition takes place the scum will be forced to the side not over the fire, whence it may easily be removed with a spoon. Thus the saucepan is held in the left hand, the spoon in the right, and the saucepan being on the left-hand side of the grate, with its right side exposed to the action of the fire, the scum will retreat to the left or cooler side, and will be in the handiest position for removal, as will be evident in a few minutes to anyone trying it. After a quarter of an hour of this treatment the mixture will have become in a great degree clarified, when it should be removed from the fire, while the top bar of the grate is let down so as to permit of its nearer approach to a greater heat. Should there be any irregularity of the fire it should now be corrected, but flame should be prevented, as the mixture having parted with its water will be liable to take fire if brought into contact with flame. It will be well here to remark that so long as the scum remained on the syrup there was a tendency in the whole to boil over, since the water evolved in the form of steam, while the boiling was going on accumulating in a body, would lift the scum above the saucepan to enable it to escape; but when the scum was gone the water would be evolved in bubbles of steam, which would crackle but not boil over, unless a very intense heat were applied. The duration of the boiling of the clarified syrup before it becomes liquid barleysugar will depend upon the amount of heat and the consequent evolution of the water to which it is subjected; but trials may from time to time be made by dropping a little on some cold surfaces to see if it becomes brittle, and when that state is arrived at it is done. Pour it into a tin dish, set it in a dry cool place until it becomes hard, and then by striking the tin on its under side the whole of the barleysugar will be splintered into fragments, when it may be placed in bottles and corked up for use as required.

"Those who wish for early swarms and strong stocks will do well to feed slowly in March or in April, even although the stock has plenty of stores; one of Mr. Cheshire's feeding stages will be found an admirable aid to effect this properly. The object aimed at should be to afford a

constant steady supply without a break. If the stage be used, as much as the bees can suck through two or three holes will be sufficient; this will be perhaps one-third or one-fourth of a pint daily. So long as this supply be kept up, so long will the queen lay and the bees tend the young; but if the supply be stopped for a day or two, and nothing comes in of Nature's providing, the bees will destroy all the young larvæ and even those almost ready to emerge should famine appear imminent. In May and June last (1874), when bad weather succeeded a few fine weeks, the bees could be seen carrying out their nearly mature young in thousands. When feeding is continued during the day as well as night, take care the supply is well protected against robber bees, or it will lead to fights and slaughter.

"Bee-keepers often express astonishment that their bees after wintering all right die in the spring. The cause is easily explainable: the stock had enough honey to last the winter, but not sufficient to supply the large demand of spring when the young put in their claims on the commonwealth.

"When a stock has become very weak and impoverished, the bees often display such lassitude that they do not accept the proffered food. In this case they may be excited by pouring into and amongst the cluster half a cupful or more of the syrup made warm; they will then set to work cleaning one another, and gain strength and inclination to make use of the remainder. Bees in straw skeps may also be fed at other times by pouring syrup in a fine stream into the combs; this will run into the cells and be afterwards properly taken care of by the bees. The quantity given must be regulated by the weather and other circumstances, bearing in mind the caution I have given as to dysentery.

"A small swarm, which if left to itself would infallibly die, may be often built up into a moderately strong stock by slow and judicious feeding, such as I have described for spring stimulation. The regularity of a small supply will induce the bees to build worker comb, and as fast as built the queen will stock it with eggs. If too much food be given it will be a misfortune, the cells being filled with honey where should be brood. Autumn feeding should be on a totally different plan to that I have been writing of—then the one object is to get the bees to store enough in their hives to last the winter. Towards the end of August every hive should be examined, and such as do not contain at least 20 lbs. of honey should be fed until that weight be reached. The weather being warm, the syrup will soon evaporate sufficiently, so the bees may be supplied as fast as they can take it. A strong stock will have no difficulty in storing away a quart of syrup in twenty-four hours. If the hive be not fully supplied with combs this liberality should not be exercised, or too much drone comb will be made, which is not desirable; better by far first persuade the bees by slow feeding to make the comb, and then give them the wherewith to fill it. It is a common practice to obtain bees by means of driving, either by gift or purchase, from those who would otherwise destroy them in the autumn for the sake of their stores. These bees, by slow feeding, may be induced to fill their hives with combs and honey, but the experiment is troublesome and costly, and those who have other stocks would find it better to join the poor eastaways to their more fortunate sisters, which will benefit all parties. Such a beaten-out stock of bees would consume 30 to 40 lbs. of honey to bring them into a fit state to winter. Syrup, as a bee food, may be made as follows, and the present low price of loaf sugar, which should alone be used (about 33s. per cwt.), is a great advantage to the bee-keeper, as this article is undoubtedly the best for general feeding. If a strong syrup be made of it by boiling with water, the sugar will either recrystallise as the syrup cools or subsequently as the water evaporates. If it be used in this form it is liable to solidify, or, as the sugar-baker calls it, grain, after it has been deposited in the cells by the bees; should this happen, they will be unable to feed upon it. This may be effectually prevented by adding to the syrup while boiling a small quantity of vinegar. The amount of vinegar necessary varies with its strength; but about a table-spoonful of that in general use will be sufficient for 4 lbs. of sugar, which will make with two pints, or 40 ozs. of water, a syrup of the right consistency, and which should boil for ten minutes after the vinegar is added; 20 ozs. of water measures a pint. Rather more water may be used early in the season, when the bees are breeding rapidly, because they then need a thinner syrup to prepare food for their young than is required for store for winter consumption. After preparing this food, put a little of it upon a piece of window glass, when it should simply grow stiffer without losing its transparency as the water dries out of it. If crystals are formed, and it becomes white and opaque, it must be reboiled with a little more vinegar. Instead of vinegar, cream of tartar may be used, of which a quarter of an ounce must be added to 4 lbs. of sugar. This food will at the present time cost about 2s. 8d. per 14 lbs., or a little over 2d. per lb.

"Honey is of course the most natural food to give to bees, but sugar syrup answers equally well and is far less valuable; and unless the source from which the honey comes is known to be pure, there is a danger of introducing with it 'foul-brood.' Foreign honey is said to be very often contaminated by this plague. Those using frame hives, where the frames are interchangeable, will often be able so to arrange their combs as to save much trouble in feeding. Some hives have more honey than they require, therefore can part with a comb or two to their poorer neighbour, and thus the stores may be equalised."

TRADE CATALOGUES RECEIVED.

Samuel Yates, 16 and 1 Old Millgate Manchester.—*Catalogue of Vegetable and Flower Seeds*

William Paul & Son, Paisley.—*List of Florists' Flowers.*
 George Templeton, Prestwick, N.B.—*Catalogue of Florists' Flowers.*
 Louis Van Houtte, Ghent, Belgium.—*Catalogue of Gesneraceous Plants.*
 Wm. Rennie, Toronto, Ontario.—*Seed Catalogue for 1884.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (W. J.).—We are not able to answer your questions. Write to Harrison Weir, Esq., Weirleigh, Brencley, Kent.

"Solidified" Sap (Ritchie).—Why do you desire us to ask Mr. Iggulden what he means by the above term? We do not remember that he has advanced any such theory as your letter indicates, and which you endeavour to controvert. If you will be good enough to point out the page in which Mr. Iggulden has employed the term you quote, and in the sense you imply, we will place the matter before him, and he will doubtless be able to "explain what is meant."

Variegated Parsley (J. W., Pershore).—The Parsley sent is attractively variegated. We should certainly save seed from the plant with the object of ascertaining whether the variety could be perpetuated in this manner, the same as variegated Kales are, and should not permit any of the ordinary green Parsley to flower in the vicinity of your plant.

Removing Bulbs (M. I.).—Narcissus and Crocuses appearing above the soil may be safely transplanted if a large quantity of earth is secured with the roots and these are kept constantly moist when out of the ground. We have often taken up such plants and flowered them in pots satisfactorily a week or two afterwards. We presume you wish to remove the plants to another garden; if so, the sooner you do that the better, as every day's delay will lessen the chances of success. If it is a question of removing them or losing them, we should certainly try the former alternative.

Primula Emperor (W. J. M.).—This very handsome Primula was shown by Messrs. Cannell & Sons, Swanley, and undoubtedly deserved the certificate awarded, for the flower is of great size, of fine substance, and excellent form.

Propagating Cornus sanguinea (J. R., Salop).—Although cuttings of this shrub will strike they will not do so with anything like the readiness of Osiers, and the usual mode of propagation is by layers in the autumn, or the shoots may be pegged into good soil at the present time.

Potatoes Diseased (T. S., Chertsey).—The tubers you have sent are affected with the ordinary murrain, and has been aggravated by a too liberal use of nitrogenous manures. We advise you to obtain a fresh clean stock, and if you use kainit in the drills at the same rate as you have used guano, and top-dress the plants at the time of hoeing with sulphate of ammonia if they are not growing fast enough, the crop will, we think, not be less in bulk, and will be the less likely to be attacked with the disease.

Fuchsia procumbens Fruits (Miss A., Carmarthenshire).—The name of your plant is Fuchsia procumbens, a native of New Zealand, where it was found by Richard Cunningham in 1834. It abounds chiefly on the east coast, growing upon the sands above the tide. It is a common greenhouse plant in England, and is pretty both in flower and fruit. The shoots may be allowed to hang down around the pots, which should be suspended from the roof if this system is adopted, or the branches may be trained over a small globular trellis, and the reddish fruits appear very attractive in this way.

Grubs Infesting Ferns (L. F.).—The insects sent are the larvæ of an abundant and troublesome weevil, Otiorhynchus sulcatus. In the autumn the parent weevils very frequently deposit their eggs at the base of the stems of various plants in pots, and the grubs feed under the earth from that season until the spring. It has been recommended in such cases to apply clear lime water freely, or a weak solution of paraffin, say a wineglassful to two or three gallons of water. Recently hellebore tea, of the strength of two ounces to the gallon, has been found serviceable as an application for the destruction of subterranean insects in pots. No insect life can resist this, and the plants do not sustain the slightest injury. We advise you, however, in repotting the plants to remove as many of the grubs as possible from the soil and destroy them. By what you say the Ferns certainly need repotting.

Loam for Potting and Vine Borders (L. L. L.).—It is not easy to determine the relative merits of different kinds of loam when the samples are as dry as if they had been half-baked in an oven. We have examined those you have sent carefully, and consider No. 2 decidedly preferable to No. 1 for Vine borders and general potting purposes. It is firmer and richer than the other, which contains little or no humus, and would not, what gardeners term, "wear" well. But then it is important to know whether the pasture from which No. 2 is taken is saturated or not, and if it is, then the soil would not be good until partially dried and aerated as in the sample before us. If

from a drained—that is, not a water-logged pasture—we should use No. 2, and add to it lighter ingredients, such as leaf soil, for such plants for which it is naturally too heavy. Although not of first-class quality, it might be made to grow most loam-loving plants well, also Vines and fruit trees. No. 1 is too poor.

Begonias for Bedding (J. R.).—Plants well prepared for beds somewhat in the manner described on page 138 last week, and planted in good condition, strong and sturdy, in rich soil, are very different in character from the tall weak fragile examples you describe as produced in pots. We have seen thousands of Begonias in beds without a stake to support them. The plants were inserted about 9 inches apart, the growths 2 or 3 inches high, and stems as thick as your finger, the tops of the tubers being placed 2 inches beneath the surface, and the soil mulched to keep it moist. The beds were a dense mass of stems, foliage, and flowers, and were not injured by wind or rain so much as Pelargoniums were. Whether they will succeed equally well in your garden we are unable to say. Much depends on its exposure, and more perhaps to the way in which the plants are treated. It would appear to us wise to try a few plants this year and gain experience, planting your bed with Pelargoniums, which you say are the "only plants able to withstand the gales without crutches." Begonia tubers may be preserved as easily as Potatoes, and planted year after year.

Cutting down Zonal Pelargoniums (F. J.).—You may cut down the plants now to any extent desired, keeping the soil rather dry than otherwise. When they have started and produced growths half an inch long shake the plants out of the pots, removing much of the soil from the roots, repotting in pots of the same size as before, or smaller, applying water judiciously, and if placed on a shelf near the glass in a warm greenhouse you will soon have dwarf healthy specimens that will flower freely during the season. Cuttings inserted now strike readily in a temperature of 60°, and well managed make excellent plants for flowering in the autumn and winter. It is quite possible the Apple may be a small specimen of Lady Henniker. It is passing strange to us that you did not give the information when sending the fruit that you give now. We note what you say about preserving the Journal; it is a good plan, and we thank you very much for your further aid if needed in the case you mention.

Smoke not Ascending Chimney (Chimney).—It is evident there is something defective about the furnace or the flue carrying off the products of combustion. Probably there is no rise from the furnace into the flue, which there ought to the extent of at least half that of the depth of the furnace, and then the flue may be taken level to the chimney, as the 2-feet rise in the flue from the furnace to the chimney is practically unimportant. We should raise the flue at the end next the furnace, so that the smoke will rise directly upwards before entering the flue, and then we think you will have plenty of draught, which is really all we can see, from the imperfect data furnished, that is needed. We cannot depart from our rule not to recommend dealers.

Making a Lawn Tennis Ground (J. T. Sinclair).—The first consideration where the soil is strong is to drain the ground efficiently, so as to prevent water lodging in the subsoil, and then fill up the drains with rubble to within a foot of the surface, to which depth the whole of the surface should be stirred, or as deeply as the good soil admits, by digging or trenching, but not bringing up any or very little of the stubborn soil to the surface. It is necessary that the whole of the soil be stirred to an even depth, so that it may settle evenly, for if hollows are filled up in order to obtain an even surface it is essential that the hills be taken down, and not only that, but be stirred to a corresponding depth with the hollows, in order to the whole sinking evenly. If the soil be of a stiff adhesive character some old mortar rubbish, rubble, or ashes may be mixed with the top foot, so as to increase its porosity, but do not put it in layers, but incorporate thoroughly with the soil. To prevent the surface becoming soapy, as heavy soils are apt to do in moist weather, add about a fourth of coarse sand to the top three or four inches of soil. If the soil be poor add some well-decayed manure, so as to favour a free growth of grass, and so form a good sward quickly. The ground before sowing should be trodden firmly, but it must be done when the ground is dry or when it does not clog to the feet. A fine tilth is necessary to be obtained before sowing the seed, which is best done during showery weather in April, and rolled immediately the surface is sufficiently dry, that the soil does not adhere to the roller.

Vine Shoots Fasciated (J. G.).—Your Vines are evidently in a strong fruitful state, and we think you will not have much to complain about when the crop is ripe. The lateral you have sent with its divided axis of growth is the result of the union of two eyes or buds, or rather the growths issuing from them, which has formed a fasciated stem. You have done quite right. We should top the lateral at one or two leaves beyond the most promising bunch, and remove the other growth entirely at the same time. The one retained will attain strength quickly, and the bunch will receive adequate support from active well-fed roots. It is not at all likely that the fasciated character will be retained, and the probability is that you will see little more of it after this season.

Cropping Vines (Cambrian).—One pound and a half of well-finished Grapes to each lineal rod of Vine is considered a good crop of Grapes, and although many crops are heavier the weight named probably considerably exceeds the average. As an example of heavier cropping, our late correspondent, Mr. Honeyman, whose portrait appears in another column, cut from a Vine two years after planting having a rod 7 feet long, 19½ lbs. of Grapes, and the following year, the rods being extended to 13 feet, the weakest Vine gave 27½ lbs. and the strongest 46½ lbs., some of the bunches weighing over 6 lbs. As to the quality of the Grapes, two of the bunches from the house were awarded the second prize at one of the largest shows in the kingdom against seventeen competitors. The Vines were 3 feet apart, and the crop was extraordinary. You may be content if you grow half a pound of first-rate Grapes from "each square foot of roof," this being equivalent to 1½ lb. per lineal rod, and the Vines 3 feet apart.

Plants in Bedrooms (Idem).—The following observations of an eminent gardener and able writer will answer your question:—"Are plants in rooms promotive of health and cheerfulness? In the case of all living-rooms I answer in the affirmative. Delicate people complain of headaches and sickness from their presence, and will, therefore, have them excluded, and

rightly too. Plants with powerful odours will sometimes produce that effect. I have known ladies that could not go near a Jasmine; others that hated Musk; some that would faint at the propinquity of a Heliotrope, and others that only approved of Mignonette when not nearer than a furlong. All of us have something peculiar in our likes and dislikes. It is rather ill natured to consider such peculiarities as mere fid-fad imaginaries. Common prudence would say, 'Keep at a distance from whatever harms you.' In bedrooms that are shut close at night I would advise dispensing with flowers having powerful odours, even though agreeable to the olfactory nerves of the owner. If he prefers retaining them it would be advisable to place them nearer the floor than the couch on which he reposes. But why not have air in the sleeping-room at night, instead of shutting it up close, when the weather is at all favourable, and thus serve the interests of the occupants and those of the plants at one and the same time? The idea of the unhealthiness of plants in living and sleeping-rooms has been suggested by our chemical friends demonstrating the influence of vegetation on the atmosphere, and the reciprocal action ever going on between the vegetable and the animal world. They tell us truly that animals are continually taking oxygen gas from the atmosphere, and throwing, by exhaling, carbonic gas into it, and that from this and other causes, but for living vegetation, the air would become impure and unfit for breathing. The solid part of plants being chiefly carbon—of which charcoal may stand as a familiar type—and every green part of a plant having the power to absorb this carbonic gas in the atmosphere during light, its quantity is thus lessened, while the action of the sunbeam enables the plant to decompose the carbonic acid thus received, to retain, add, or assimilate the solid matter (the carbon) to itself, and to set the other constituent (oxygen) free for the benefit of the animal world. Thus it would seem that the nearer we get to healthy vegetation the more likely we shall be to get the benefit of this fresh-forming oxygen; but, as if to damp our enthusiasm, we are presented with a lesser and a greater drawback to our satisfaction. This lesser is, that all unhealthy parts of a plant, yellow leaves, &c., and, what is more painful still, all flowers in proportion as their colour recedes from the green, vitiate the atmosphere rather than improve it even during the day. The second drawback is, that at night, or in darkness or much shade, even healthy plants exhale carbonic acid gas and inhale oxygen, and just in proportion to their size and powers deteriorate the atmosphere like ourselves, and therefore become, especially after twilight, very undesirable neighbours in our dwelling and sleeping-rooms. To this heavy accusation I reply that, in general, the size of flowers, in proportion to green leaves the plants grown in rooms, is so small that during the day the advantage greatly outweighs the disadvantage; and though undoubtedly plants do give off carbonic acid gas at night, yet at that time the rooms are generally at their coolest, and as this gas is something like three to two heavier than common air, it will, in such circumstances, fall to the floor, and only be mingled with the general atmosphere by the heat and the sunshine of the following day. Unless the plants were extra numerous the absorption of oxygen would not much influence the air of the apartment. All or almost all injury might be avoided by seeing that the plants were lower than the seat or couch of the owner. I believe this the more because dew, the condensed moisture in the air near the ground, holds much more of this gas in solution in general than common water does. On the whole, then, unless in the case of delicate invalids, or of plants with very large flowers or having a powerful odour, I believe that healthy plants in rooms are decidedly beneficial, and promotive alike of cheerfulness and health, and that this is especially the case in large cities and towns." To that we have only to add that a very large number of plants would be needed to vitiate the air so much as would be done by one adult individual. Hardy Ferns may be planted just as they are commencing growth.

Names of Fruits (*G. Randall*).—Golden Knob. (*G. Cummins*).—Dumelow's Seedling.

Names of Plants (*C. E. T. M.*).—Helleborus guttatus. (*H. S.*).—1 Ruscus hypophyllum; 2, Eleagnus variegatus; 3, Eurya latifolia variegata (*G. R. J.*).—Centaurea candidissima. (*W. G., Leeds*).—A poor variety of Lælia superbiens. (*W. D.*).—The flower was almost unrecognisable, but it resembles Philadelphus coronarius. (*W. J.*).—Rhodora canadensis. (*James Woods*).—As we stated last week, and many times previously, we do not undertake to name Camellias nor varieties of any florists' flowers. See page 139

GRASS SEEDS FOR LAYING DOWN LAND TO PERMANENT PASTURE.

(Continued from page 140.)

HAVING discarded all ideas of obtaining any advantage by the growth of any variety of Rye or Ray Grass, what varieties shall we substitute for the heterogeneous mixtures to which we have been recommended by the various firms and seed establishments in different parts of the kingdom? The reply to this question it must naturally be made a matter of soil and climate. In describing these the seedsmen have in various instances well set forth the soils by placing them in separate divisions for adjusting the sorts and qualities of seeds per acre. Therefore we cannot do better than adopt these divisions in most cases, and furnish a list of seeds which we, through the experience of Mr. Faunce de Laune and our own, recommend as the best varieties to be used, together with the quantities of each per acre. We have still numerous varieties of permanent Grasses from which to choose, after having discarded all and every kind of Rye Grass. We will therefore choose those varieties, including some Clovers, best adapted for our purpose for seeding upon certain defined soils, taking first the strong clays called tenacious and London clays. We propose to seed them with the Grasses and quantities per acre as follows:—

	lbs.
Dactylis glomerata (Cock's-foot)	12
Phleum pratense (Timothy or Cat's-tail)	4
Cynosurus cristatus (Crested Dog's-tail)	5
Festuca elatior (Tall Fescue)	4
Festuca pratensis (Meadow Fescue)	4
Alopecurus pratensis (Meadow Foxtail)	4
Trifolium pratense perenne (Cow Grass or Perennial Red Clover)	4
Trifolium repens (Dutch Clover)	4
Total quantity per acre	41

We choose the sorts of seed here enumerated not only as well adapted for the soils named, but because they are recognised by a great consensus of opinion by practical and experienced authorities, but by many firms of seedsmen whose experience justifies our selection. To satisfy the home farmer, our readers, and farmers generally it will be necessary to take first, and give the qualities and general value as to permanency. Commencing with the Cock's-foot, this is by far the most valuable of all Grasses, because it grows in all soils, it produces the greatest amount of keep, it is the most nutritious Grass, and seems to grow faster and stronger in extremes of weather, either wet or dry, than any other Grass. There is, moreover, hardly any stage of its growth in which stock do not eat it greedily, and its flower heads appear to be especially nutritious to all kinds of stock, young or old, in excessively wet weather. Cock's-foot has no chance of seeding, unless there is a great abundance of it and the stock are running light. Cock's-foot is often objected to, as it is said that stock pull it up by the roots; but it will be observed that it is not the centre root but the side shoots that are lying on the ground, Cock's-foot being different from the other permanent Grasses in its growth. It also grows quicker than any other permanent Grass after having been mown, and its long leaves may be invariably observed wherever it is present in a meadow after it has been mown for hay. On this account it is extremely objectionable in lawns or cricket grounds.

Timothy or Cat's-tail commences to grow about as early as Cock's foot in the spring, and bears feeding-off remarkably well, as it seems to produce as heavy a crop in summer after having been fed-off in the early part of May as it would have done had it not been so fed-off. It is, like Cock's-foot, never allowed to seed by the stock, for its flower-heads are extremely grateful when the seed is ripe to both young and old animals. This Grass is much objected to by many on account of its apparent coarseness, but as all stock like it there is no force in the objection. The aftermath of this Grass does not appear so strong in growth as that of either Foxtail or Cock's-foot.

Crested Dog's-tail is found everywhere. The roots penetrate deeply, therefore it retains its freshness and successional growth for a longer period than most other Grasses. It is an essential element in mixtures for permanent pasture, as it forms a close dense turf

of nutritive herbage, and in consequence of its deeply rooting is little affected by extremes of weather.

Tall Fescue is amongst the most valuable of pasture Grasses, and is also one of the most productive and nutritious of British Grasses. It is greedily eaten by cattle and sheep, and all stock thrive well upon it. It is, however, a somewhat later Grass, and of a more robust habit, but is nevertheless very valuable for its aftermath. Meadow Fescue is another valuable Grass that in all its stages of growth is liked by stock. It is much the same in its growth as Tall Fescue, but not quite so strong in the blade, and it has, since its more general growth by practical men, increased in their estimation as being well suited for strong soils, for it is both hardy and deep-rooting.

Meadow Foxtail is one of the most valuable Grasses of the farm. It is about one of the first to flower, gives a good bulk of produce, and grows well in any soil where its roots can freely penetrate, and is strictly permanent in its habit of growth, and possessing, as described by a celebrated writer, "the three great requisites of quantity, quality, and earliness in a superior degree to any other." At any rate we may be sure it is particularly adapted for moderately stiff clay and heavy loamy soils, and under favourable conditions will produce a greater weight per acre than most other varieties of natural Grass.

Cow Grass or Perennial Red Clover is well suited to clay soils, for it is very hardy and very productive, and should be used in all seed mixtures for such soils as we are now referring to. It is of a distinct kind from the Red or Broad Clover used in alternate husbandry, for the former has a solid stem or stalk, whereas the latter has a hollow stalk. Cow Grass blooms rather later than Red Clover, and does not yield a second cutting so fully or quickly, but is immensely productive upon heavy soils overlying the chalk.

The last seed on our list is Perennial or White Dutch Clover. This is of much importance in all permanent pastures, especially those used for bullock grazing on strong soils, such as we find in the midland counties, and in fact in parts of various districts in the kingdom. The distinctive character of this is the smaller leaf and close creeping habit of the permanent plant, which is very tenacious of the soils of which we are writing, and is quite different from the strong luxuriant growth of the Giant White Dutch used for alternate husbandry.

All the sorts of Grasses which we recommend for use upon the new and improved style of laying down strong and tenacious clays to permanent grass have been described; still there is and must necessarily be something rather vague in the words "strong and tenacious clays," because it depends very much upon the underlying soils, for if it be chalk, limestone, gravel, or sand a certain amount of porosity will exist in the surface soil, and in the case of chalk and limestone subsoils there will frequently be found nodules of carbonate of lime and marl, which are highly favourable in conjunction with any strong soils, and greatly ameliorate the nature of the clay, be it ever so strong; but when the land is composed of strong clay, only both on the surface as well as subsoil, it will require special cultivation, and on this point we will quote from an article by the late Mr. T. Carrington (Journ. Roy. Agric. Soc., vol. xv., p. 490), than whose opinion there are few more valuable. He says: "No person who has not had experience will appreciate fully the difficulty and tediousness of the operation of converting into really good turf poor strong land which has been constantly under the plough for generations, and in which every bit of vegetable matter has been used up by the practice of having periodical dead fallows dressed with lime." Three points in this quotation are prominent, which refers to tediousness of the operation, the loss of all vegetable matter, and the consequent unworkable state and tenacity of the soil. Taking these points fully into our consideration we have discarded all idea of attempting to grow any variety of Rye Grass, but have introduced those Grasses which are not only permanent but adapted to the soil; and we may safely say where the soil is made rich enough and well tilled before sowing, that a quick and lasting turf will be acquired without the interval so commonly complained of and called tedious by Mr. Carrington. To effect and obtain the other two requisites we recommend that a fallow made by the growth of green crops, and ploughed in as described by the essay on Mr. Peter Love's system of growing successional crops of Mustard and other suitable green produce will be not only made clean, but will be manured simultaneously in the best possible manner; for these and vegetable products in their death and decay will enrich the land and open it, making it porous enough to admit of free rooting for the Grasses, and at the same time furnish humus and vegetable matters with a certain amount of nitrogen, potash, and phosphoric acid for the sustenance of all the Grasses in their infancy, and hold them on with future good management so as to furnish a good turf, by retaining those Grasses which we have recommended in permanency.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—In the pasture districts, especially in those cases where the produce has been removed for hay or ensilage, and also where dairy produce has been sold away either in milk, butter, or cheese, the horses should now be employed in drawing out any compost manure which may have been provided for the purpose, and which should be spread immediately after being laid on. Where no provision has been made of dung or compost, which is too often the case, as farmers are very apt to neglect the pastures and apply all the manures arising on the farm to the arable land, where the extent of arable is considerable. This, however, is not economy, because the artificial manures—such as bone superphosphate, nitrate of soda, and guano—may be applied with most advantage to arable rather than pasture land, simply because almost any addition to the grass land, like composts, yard, or town dung, which have bulk, are sure to answer best, for on the arable, where an increase of soil is to be obtained by deeper cultivation, renders bulky manures unnecessary compared with pasture. In the hand manures we obtain the elements of manure without much substance, the only requisite being dry ashes to assist in the equality of distribution, or when sown by hand damp ashes to prevent the light manures from flying before the wind, more especially when applied for Potatoes in the furrow with the sets. In various pasture districts where cattle are grazed and fattened for the butcher, and especially where they receive cake while grazing, manure will not be required to maintain them in good heart and condition; but where the pastures get no bulky manure the hand tillages should be applied as follows:—3 to 4 cwt. of bone superphosphate per acre applied in February, and 1½ to 2 cwt. of nitrate of soda per acre applied in March, both to be sown broadcast.

Barley-sowing may now be done the first chance when the land is dry enough to work freely, for we hold that it is better to sow Barley early than Oats, because the early-sown Barley will usually produce the best malting samples, whereas Oats, if sown in the middle of March, will generally go on without much check; nor can we very easily produce an overcrop of straw to injure the yield. An experiment of ours some years ago is quite in point, for we once tried one half of a field sown with Barley and the other half with White Canadian Oats. The Barley gave nine sacks per acre of inferior grain, and the Oats yielded nine quarters, weighing 45 lbs. per bushel. Both samples were sold in the same market, on the same day, to the same dealer, at the same price per quarter—viz., 28s. 6d. per quarter. We have not since committed such a mistake as to sow Barley upon loamy or mixed soil in good condition, but we prefer following out the lesson taught by the comparative experiment.

Live Stock.—In early lambing districts of the southern and home counties, where the horned Dorset ewes are some of the forwardest, lambs will have been sold, others must be nearing maturity, and the ewes also should be advanced in condition as much as possible in order that they may be sold at the same time as the lambs, or as soon after as possible; and in all those cases where both ewes and lambs may have been fed with the best food, still the finishing process of fattening will be best completed by giving bean meal in admixture with the cut roots, both for ewes and lambs, the quantity to be arranged according to the cake, which they may have previously received as their daily allowance. The young cattle, both steers and heifers, should be kept in well-littered and well-sheltered yards; and although they may in various instances go out at day time and obtain a little grass, yet a few cut roots, with 2 lbs. per day of cotton cake in admixture with middling hay, will keep them in good growing condition, and forward them for entry upon the summer grazing on the pastures; and in the case of heifers this management will prevent them from suffering from quarter-ill or evil, to which they are subject more than steers, if they lie out at night time on the pastures. Dairy cows, too, will soon be ready for calving, and should be fed accordingly, but not if possible so as to accumulate internal fat, which endangers their lives by puerperal fever or the drop at calving time. Working horses should continue to receive about 12 lbs. per day of roots, either of Carrots or Swedes, later on of Mangolds.

REMARKS.

- 10th.—Squall at 4.10 A.M.; showers, with hail, at intervals all day; thunder and lightning at 11.50 A.M.; fine evening.
 11th.—Fine early; thunderstorm 0.7 to 0.15 P.M., with much soft hail, rather more than half an inch in breadth and length; occasional showers afterwards.
 12th.—Fine throughout.
 13th.—Very fine day, with warm sun; shower after 9 P.M.
 14th.—Fine and warm, but a little rain at night.
 15th.—Much colder, with piercing wind in evening.
 16th.—Cold but fine throughout.

A rather variable week, including some very mild and some cold days. The temperature of the week as a whole considerably above the average.—G. J. SYMONS.

ROSES—THE COMING SEASON.

UST as the sap rises in our Rose trees so does the latent heat of our Rose-growers, especially our Rose exhibitors, begin to develop itself, and on all sides questions are continually asked upon many points connected with the flower. What sort of a season do you think we shall have? Should we prune early? What is the condition of your plants? These and other questions are constantly coming before me, so that our interest in the flower is kept constantly on the move. Before making any forecast, which perhaps, like those of the Meteorological Office, are as likely as not to be wrong and to be upset by some "disturbance" or other, we cannot be very far wrong in speaking about the past. Surely such a season has never been recollected by "the oldest inhabitant." We have now reached beyond the middle of February, and have had no winter. The weather has frequently been as warm as in May or June. Indeed on the 12th of this month the thermometer stood at 55° in the shade, and it would have been regarded even for the leafy month of June as a lovely day. Spring flowers are long before their ordinary time of blooming, Primroses are plentiful in the woods, birds are nesting, Nuts are flowering and Roses pushing, indeed in many of them I have seen well-formed buds. These are of course at the extremities of the shoots, and the question naturally arises, What will be the effect of these on the future well-being of the plants? Does it not take so much vigour out of them? and as the sap is rising so rapidly, will there not be considerable bleeding and consequent deterioration of the plant? With regard to the first of the questions, I do not think that we can say that it would be more injurious than what we have so often experienced when we have had to cut and cut away because our Rose trees have been severely bit by frost. We had the same sort of winter last year, although not so mild; but there was the same chorus of howling dervishes over the lost hopes and the impossibility of finding good Roses after such a season, when all the vigour had gone out of the plants owing to their premature growth in the early part of the year. And yet there *were* Roses, and good ones too, and trees that had been all a-growing in February, and were even cut back after pruning in that terrible fortnight in March, did somehow or other throw out lustily, and made good bushes again before the autumn. Who that saw, for instance, the rows of Marie Baumann at Mr. G. Baker's at Reigate could have believed that they had been so situated, had grown early, had been pruned early, had been caught by that severe frost in March, and had to be again pruned? And yet there they were, models of growth and health. In truth, we begin to see that the Rose will stand a great deal more than it was at one time believed that it could.

As to the appearance of the plants, I have seen them in many places north and south, and everywhere they look well. The wood seems to have fairly ripened and the shoots are healthy-looking. I have been surprised, too, to see how little difference there is between their condition in the north

and south. Certainly the most forward shoots that I have seen were in the garden of my friend Mr. Hall in Cheshire, where rather plump buds of A. K. Williams were plainly discernible on the top of the long shoots. I had nothing so forward amongst my own plants; but then the soil in Mr. Hall's garden is perfection, and its richness may have contributed to this result. I therefore with some confidence look forward to the season of 1884. There have been no such deaths as occasioned by a severe winter, and good and generous treatment will, I have no doubt, supply all that is wanted to enable the trees, even after their vigorous pushing out, to put forth renewed powers.

As with the trees so with those who grow them—the sap has begun to rise, and the dates of exhibitions and the drawing-up of schedules are engrossing many minds. The Metropolitan Exhibition of the National Rose Society will take place on July 1st, as announced. The date of the Salisbury Show is unquestionably later than desirable, but it is one of those cases which mark the difficulty of making arrangements: they cannot have an exhibition except on one day in the week (Wednesday), and as we cannot of course have two National Shows on consecutive days, they were perforce compelled to have it on the 9th instead of the 2nd of July. Then, again, I am engaged in an animated correspondence to settle the conflicting claims of Manchester, Liverpool, and Darlington as to dates. There are wheels within wheels, and reasons weighty and numerous brought forward on all three sides, but owing to the loyalty of those engaged in the triangular duel I believe all will be satisfactorily arranged; but only those who are behind the scenes can know the difficulties that surround the attempt to arrange all the shows which must be held within the space of three weeks. As to the southern shows Canterbury will, I believe, lead the van on June 26th. Then follows Reigate on June 28th, the National in London on July 1st, Farningham on July 3rd, Sutton on July 4th, the Crystal Palace, and probably Brockham, on July 5th. West Kent will very likely be either on Saturday June 28th or Saturday July 5th. Maidstone is not yet fixed, but will probably be on the first week in July; and although our veteran friend, Mr. John Hollingworth, has been sadly shaken by his severe attack of illness, yet we are all hopeful that on the return of more genial weather he may be able to look after his "beauties," and may be the victor on many a tented field. There are other exhibitions of which I have no notice as yet, but those named are the principal, and it shows that there is no lack of interest in the flower we look upon as *facile princeps*.

A change has lately taken place in the weather which I cannot but look upon as favourable to our prospects. The wind has come round to east and north-east, dry and cold, with slight frost at night. This will check too rapid growth, and will prepare the wood better for pruning. I see all the prominent shoots are already feeling its influence, and if it continue there will be less probability of the severe frosts such as we had last March.

I have been asked by several persons as to the Rose support invented by my neighbour, Mr. Foster, to give his address. It would be premature to comply, as he has, I believe, declined in some instances to give a sample, because he felt that as it was not patented the sample might be used as a pattern, and he thus be deprived of any benefit arising from it. My opinion of it is very decidedly in its favour. It saves the exhibitor all the trouble of wiring, as it is done in an instant. Mr. Foster's tubes seem also to be a great improvement; for when the Rose has been put into the wire and placed in the upper portion of the tube it can be simply lifted out and placed in any other portion of the box. Exhibitors know well how often this has to be done, and oftentimes with a great deal of trouble, but Mr. Foster's plan makes it as easy as possible. He is trying to arrange some plan in connection with it so that the name of the flower may be removed at the same time, thus enabling the exhibitor to avoid that terrible word

"disqualified," which may have been placed on a box through the confusion consequent on these frequent removals in order to make a box look more symmetrical.

The increase in the number of growers and embryo exhibitors, and the enlargement of the roseries of those who are already such, indicate that we shall have no lack of interest in the coming campaign, and if all goes well there will no doubt be an exciting Rose season.—D., Deal.

DIGGING—A CHAPTER FOR BEGINNERS.

As the plough is the first requisite on a farm so is a spade the most important implement in a garden. I am afraid, however, that gardeners as a rule do not strive to surpass each other in the use of the spade, as ploughmen do in turning up the square straight furrows so pleasing to the eye of a farmer. I daresay some nursery foremen, who see as much spade work as most men, would be able to say that not a few head gardeners who come under their eyes are not over-perfect in the use of a spade, and it is therefore less surprising to find many young men use it in an indifferent manner. But few gardeners get far through life without having to avail themselves of that often-welcome shelter—a nursery. The experienced eye of the nursery foreman soon gauges a man's capacity for digging when he has him a few times across a square amongst some dozen others. In such a position the man who is not skilled in the art will soon find that mere brute strength will not enable him to cope with his more weakly neighbour who has had more practice. Digging is hard labour to anyone, and nothing but actual practice will perfect a man in the art of doing a certain amount of labour with the least exertion.

The necessity of digging and trenching, when it is best done, and the reasons for doing so, are frequently written about; but is the simple operation of turning up the soil of so little account as to receive only a passing notice?

In the first place let me point out the desirability of every youth accustoming himself to work his spade with either hand. When he first starts to dig he will find it quite natural to lift the spade with one hand only. Sometimes it is the right, while in others it is the left; and if he goes on without making an effort to use the other he will find it the more difficult to practise afterwards. Apart altogether from the fact that a man who can work with either hand has an advantage in that while one arm is lifting the other is resting, it does not look workmanlike to see men digging backwards across a square. This is especially noticeable when a few men are at work together and following each other.

A young spademan often makes the mistake of not keeping a sufficient opening. He allows the soil to come forward so as to interfere with the lifting of the next spit, and then he finds he must throw some back on the top of the other, which may not improve the levelness of his work. When digging ground about to be cropped it must be well broken up, not only on the top but at the bottom also. Never dig with a spade amongst fruit trees or shrubs; always use a fork, and that carefully not to break surface roots. In turning up the soil in the autumn or winter the great object is to expose as great a surface to the action of the weather as possible. It should therefore be left rough. When trenched it is left in ridges. After these have been frozen, and when sufficiently dry, they should be levelled down, using digging forks, and again left rough. A few late frosts and drying winds will make soil so cultivated into the best possible state to receive the seeds and perfect a crop. All kitchen garden ground should be regularly trenched every three or four years, and by breaking up the bottom the soil is gradually made deeper without bringing much of the subsoil to the top.

Simple ridging is sometimes practised on heavy lands. This I have discontinued. It involves little more labour than ordinary rough digging, and does not give a proportionate advantage. Having great faith in deep cultivation I prefer double digging. A good opening is first taken out about 15 inches wide and two spits deep. No line is used, as in trenching, but it is slightly nicked with the spade, only a couple of inches wider than the spade, keeping as straight as possible by sight. The ground is then dug over the same as in trenching two spits deep, the only difference is in the treatment of the bottom spit. Instead of tossing it down roughly, as in ordinary rough digging, we set them up leaning against each other cornerwise on the generally more loose top spit. To get these little miniature ridges to stand requires a little practice. The workman must stand in the trench, so that the hand he is lifting with is towards the dug ground. He must only lift moderate

spadefuls, and set them gently but firmly down on one corner, leaning against the last spit. Ground so dug is quite as well exposed to the weather as in any other way; it looks neat, and it does not require any second moving before being cropped, as it is generally done when trenched or ridged.

In digging avoid that slovenly way of pushing the spade into the ground anglewise; send it straight down, and the spit will come up the easier. Also avoid stooping as much as possible. In rough digging the workman should stand up to his full height, or nearly so, every time he lifts his foot to take a fresh spit. It is the continual stooping more than the weight of the work that makes the back ache. Another practice to be avoided is the cutting of heavy soils into great square blocks, as I have often seen done. In ordinary or double digging let the spits be only about 4 or 5 inches thick; and in trenching it is preferable to lift it in triangular pieces without any after chopping.—R. INGLIS.

KEEPING VINE ROOTS NEAR THE SURFACE.

I WAS pleased to see Mr. Thomson's description of his excellent method of treating Vine roots on page 58. I had the pleasure of seeing the Grapes at Drumlanrig a few years ago just when they were finishing, and they were simply splendid, fine-sized bunches with enormous berries, and what was more remarkable it did not matter whether the bunch was held horizontal or perpendicular, the berries never shifted, and the bloom was first-rate, especially of the Black Hamburgs, which is the favourite variety there.

Perhaps a few remarks upon my experience with Vines may not be out of place. I entered a situation over six years ago where there were two large vineries, in which the Vines had been planted seven years previously, but had never given satisfaction, and my instructions were to grow them better or pull them out. As the glass house accommodation was rather limited I resolved on doing something at the foundation and give them a fair chance. I waited patiently until the last week of February, and was favoured with fine mild weather. The Vines had been planted far too deep, and the roots had grown straight out into the border. I could not find a root nearer the surface than 20 inches. The soil was taken out at the end of the border to within 3 or 4 inches of the bottom, and the whole of the outside border was turned over, lifting the roots very carefully and relaying them again among fresh loam within 9 inches of the surface. The border was then covered with manure from the farmyard to the depth of 10 inches. One foot of the soil at the top of the inside border was then drawn carefully back to the roots, and some fresh loam applied to encourage them.

The Vines started their lateral growths very slowly until the fruit was seen, then they rested for about fourteen days. At this stage the vineries were kept rather close and syringed lightly several times daily. Then they started again and did wonderfully well considering the ordeal they had passed through, and the result was the bunches were rather small, but proved satisfactory when sent to table. The inside border roots were lifted in the following spring rather nearer the surface (within 6 inches); and I have since treated our Vine borders annually something similar to Mr. Thomson's method, except that the ingredients were not quite the same. I am now using the Vine and plant manure sent out by the Liverpool Horticultural Company, and without doubt this is a useful manure for the Vine. It is applied occasionally the same as we apply guano, stirring up the surface first and washing it well in.

Another important matter is watering Vine borders, especially those inside. I quite agree with all Mr. Muir said in these pages some time ago about giving copious waterings. The tank here measures 9 feet long, 4 feet broad, and 5 feet deep, and this is emptied within 15 inches of the bottom frequently during the growing season (the dimensions of the borders being 30 feet long by 15 feet wide), but the water is first warmed to the temperature of 70°, sometimes above but never below it. There is a large furnace pot adjoining at the back, which answers this purpose admirably. Tepid water I consider a great boon to Vines, and more especially in the early part of the season. I would like to ask your readers what is the use of making such deep borders (except it be to retain moisture), seeing that Vines do well with their roots near the surface, where they can be fed annually, and it so happens that suitable soil is sometimes difficult to obtain. Of course the rainfall for the district should be taken into consideration; the rainfall here is very heavy. I would like to hear what Mr. Thomson and other good Grape-growers have to say on this point—depth of border.—J. J. C.

EARLY PEAS.

PEAS which were sown in pots the last week in January and treated during the interval as recommended at page 61, will now be ready for transplanting in a warm border in rows 4 feet apart, which, for dwarf-

growing varieties, will be sufficient space between the rows. They should be turned out of the pots carefully, having previously placed a short stick and a piece of matting to each plant for support, and planted with the garden trowel 9 or 12 inches asunder in the row, disturbing the roots as little as possible in the operation. This being done, a little soil should be drawn up to the plants on each side, and then a mixture of lime and soot strewn on each side the ranks of Peas as a protection against the ravages of slugs; then stick them in the ordinary way, putting the two rows of spray sticks sufficiently close to each other to prevent the haulm swaying, and if necessary stick a few Spruce boughs in the ground on the cold side of the rows for a few days until the Peas are completely inured to the weather. After this, in the absence of frost or cutting winds, which are almost as injurious to the young haulms as frost, they should be removed.—H. W. W.

PAINTED VERSUS GLAZED POTS.

REFERRING to Mr. Henderson's remarks (page 143), I think if he will consider that glazed pots can be manufactured at a cost of one-fourth more per cast than ordinary pots he will not have much difficulty in concluding that to put two coats of oil paint on ordinary pots (taking labour and material into the count) will be the more expensive of the two processes; besides, the constant moisture both inside and outside would soon destroy the paint. I have tried the silicate process (dipping the pots in silicate), which so filled up the pores that the pots did not get so soon dirty and green as under ordinary circumstances; but this is all that I can say for the process. I am quite satisfied that if the owners of private gardens could be persuaded once to substitute the glazed pot for the common one they would never begrudge the trifling cost nor revert to the old dirty pot. Let the demand spring up, and it will be odd if makers do not come into the field who may make glazed pots even cheaper than I have indicated.—D. THOMSON.

I HAVE tried the plan of painting flower pots, as suggested by Mr. H. Henderson, with body paint, and decorated them with flowers, &c., of the same material. They look well, and have sold well at local bazaars. A pleasant employment for young gardeners to try their hand at artistic work. But when the pots have plants in them, and regularly watered, I find the paint shells off, so they would have to be used with another pot dropped into them. I supply the cottagers with plants for their windows, and their plan is to give the pots a dressing of red lead and milk. These pots come at times to be refilled, and I find they keep their colour and seem to stand the moisture.

Painted tubs, as stated by Mr. Henderson, answer well with me, as I have red and white *Lapagerias*, *Oranges*, *Passifloras*, *Tecomas*, &c., in them, all growing with the greatest luxuriance.—BLACK PRINCE.

NEPENTHES.

FOR decorative purposes Pitcher plants have a peculiar fitness; their unique and elegant appearance renders them particularly attractive when general plants would be passed without comment. The prevailing idea that they require to be kept in health by a high temperature and an atmosphere saturated with moisture is being slowly exploded. The cooler treatment to which they are proved to be amenable is likely to open up a wide field for the employment of these plants for the decoration of the dining table, and especially for grouping with other plants in halls, corridors, and staircases at party times. A short sojourn in such positions not exactly suitable does them no great harm provided they have been grown in a cooler and somewhat drier treatment for a brief period before being subjected to the ordeal of decoration in the house.

The present time is a suitable one to attend to their requirements, no plants better rewarding the care bestowed on them. Small plants will need a shift into larger pots. If in a 3-inch pot a 5 or 6-inch pot will be a sufficient shift, and those in larger pots will need correspondingly larger sizes, always provided the plants are in a healthy condition at the roots. Good drainage, although *Nepenthes* are semi-aquatic, is of great importance. It should be about a third the depth of the pots, having the largest crocks at the bottom, finishing with the smallest, securing with a layer of sphagnum, or preferably lumpy peat, the dust being shaken out as the peat is pulled in pieces. Brown fibrous peat pulled to pieces, the coarse roots picked out, and those with the smaller particles of the peat rejected, fibrous lumps only being used for potting. Sphagnum does no good, as, mixed with the peat, it soon decays and becomes sour, but a few broken crocks and pieces of charcoal in various sizes keep the material open and sweet. If sphagnum be employed at all it is best as a live covering for the surface. In potting remove all the soil not occupied with roots, and though as much of this as can be picked out from the roots as can be done without injuring them, there must not be any attempt at disrooting. Pot rather firmly, and dash a little coarse silver sand on the surface when the potting is completed.

The best mode of growing and displaying *Nepenthes* is in baskets, for which teak is the best material; 1-inch square strips with the edges bevelled answer for the largest size, which may be about a foot square and about 6 inches deep. This size will accommodate the

largest specimens, the depth being proportionate to the size. Lumpy peat as above described is the proper material for basketing. If it be not desirable to shift into larger baskets the old sour material should be removed and fresh supplied, also in shifting into larger baskets or new remove as much of the old material as practicable without injuring the roots. If the baskets are neatly lined and surfaced with live sphagnum it will add to their appearance.

There is no disputing the luxuriance *Nepenthes* attain in a high temperature with plenty of atmospheric moisture and shade, and it is also certain the growth is lank, the pitchers lacking the size, substance, colour and durability of those formed in a lower temperature, and shade only to prevent scorching. At night 60° to 65° is ample, and 70° to 75° by day, and 80° to 90° with sun during the growing season, and when at rest 55° to 60° at night, and 5° to 10° rise by day according to the weather.

They must never become dry at the roots, and when growing water can scarcely be given too copiously provided it be soft and warm and percolates through the compost freely, passing away as if through a sieve. Atmospheric moisture must be maintained by damping available surfaces two or three times a day, and the plants also when growing, more especially at closing time, which should be early, air being given early in the day. It is essential that there be no heavy syringings, but gentle sprinklings, and a little water kept in the pitchers will assist them to retain their freshness. The nearer the plants are to the glass the stouter will be their texture, and this, with plenty of light, will afford finer and better-coloured pitchers than those grown at a distance from the glass and heavily shaded, besides adding to their usefulness for decorative purposes through their firmer and more persistent texture. When at rest lessened supplies of water and moisture are needed, but a sharp look-out must be kept for thrips, which should be at once expelled.

In the spring or about March the majority of the plants will need shortening, as they are apt to become tall or straggling, which will have the effect of producing new growths at the base as well as increasing their number, and it is on these new growths that the best pitchers are formed. The parts removed may be utilised as cuttings—i.e., the firm part of the shoots, for the soft-growing points are unsuitable, it being the firm wood only that will root and push growth freely. Three at most, or, if the cuttings be scarce, two joints, are quite sufficient for a cutting. These should be placed in equal parts of fibrous peat, small charcoal or small crocks, and chopped sphagnum, with a sprinkling of sand, or they will strike freely in cocoa-nut fibre refuse, placing them in a frame where there is a brisk heat, and they will root slowly but surely. The leaves may be shortened about half or be tied-up loosely. It is essential that they be kept moist. When the cuttings have rooted they should be gradually inured to the atmosphere of the house and the lessened temperature, and then transferred to larger pots, or preferably small baskets in peat fibre, suspending from the roof of the stove, giving them plenty of moisture, and keeping a sharp look-out for thrips, which, allowed to have their own way, will spoil the appearance of the plants. For general usefulness *N. Chelsoni*, *N. Hookeriana*, and *N. Rafflesiana* are probably the best. *N. sanguinea* is very desirable, and such forms as *N. ampullacea vittata*, *N. albo-marginata*, *N. Dominii*, *N. hybrida*, *N. gracilis major*, *N. maculata*, and *N. intermedia* are very effective.—G. ABBEY.

THE USE OF SPRING WATER IN GLASS STRUCTURES.

It seems almost superfluous to affirm that the use of spring water, whether as applied to the roots or the foliage of fruit trees and other plants under glass, is at least a very objectionable practice. It is, however, a well-known fact that many have no other source of supply, and are therefore compelled to use it almost constantly. In some districts such water is especially dangerous owing, as Mr. Abbey has remarked, to the injurious mineral substances it contains, notably when much iron or lime are present. With these facts in view it was with no feeling of complacency that I found myself last season compelled to resort to spring water as a main supply. The probable event in particular of the inroads of the usual insect pests created uncomfortable forebodings, well knowing that the limited supply of rain water at my disposal would prove a serious obstruction in dealing effectually with the enemy with the syringe. I am, however, glad to say that my apprehensions were not realised, at least to any great degree; for although the foliage of Peach trees in particular was not so healthy for a short time as I could have wished, there is no evidence of the present year's crop of fruit being endangered, the same giving promise of being at least equal to last year's, which was more than an average one. Referring to root-waterings, I resolved to reduce the necessity for these to a minimum, and accordingly had all the inside Vine and Peach borders mulched on the surface with a few inches of farmyard manure. One large span-roofed vinery border was covered with cowdung owing to the greater extent of glass surface exposed to the sun. Unless when forced to do so in order to combat insect life I never syringe Vines after they are fairly started. Last season, the foliage being healthy at all times, I am glad our spring water did not require to be tested further than damping surfaces and watering the borders.

Although in my experience the use of spring water has not hitherto been attended with perceptible injury to fruit trees, including Vines and Peaches, to the cultivation of which the glass structures here are devoted, I should not be surprised to know that there are instances in which its use is followed by less favourable results. In some localities the access of surface water from shallow drains neutralises the injurious properties of spring water.

Another word here. I have often felt it not a little tantalising to see the rain water from hundreds of yards of roofing finding its way into the waste pipe, which with ample and convenient cistern accommodation would prove an invaluable boon to the gardener, besides facilitating many of his most important operations.—D. MACKIE, *Ayrshire*.

CURRENT-BUD MITE.

WITH this I send a branch of Black Currant, which you will see is very much affected by a disease known here as "knotted." There are many trees so affected in this neighbourhood (Liverpool), and all my

Fig. 31.—"Knotted" Currant shoots.

gardening friends are, like myself, at a loss either to account for its presence or to cure it when once established. I was totally unacquainted with it till I came here nine years ago, and as the trees here were very old I thought age was the cause. I therefore propagated a fresh stock, which should now be doing some good, but which, I am sorry to say, are nearly all more or less affected. If you or any of your readers know of any remedy and will kindly publish the same you will confer a great benefit on many besides myself. I scarcely need add it is useless to expect any fruit from such diseased buds.—T. W.

[We have had two other letters from Lancashire and one from Scotland of the same purport as the above, and they indicate that the Currant-bud Mite is spreading and seriously injuring plantations of the Black Currant. One of the sprays sent to us we have had figured, and we know from experience that bushes that are covered with

similarly enlarged buds can produce no fruit. The subject is therefore one of considerable importance. The knotting is caused by an insect which we fear is not easy to extirpate.

The Currant Mite (*Phytoptus Ribis*) belongs to a rather extensive group of minute creatures, which are by some naturalists placed amongst Crustacea, and by others classed with insects. Present opinion, however, rather tends to put them, with sundry allies, in a group called Aptera, insects the wings of which have somehow disappeared, and legs and transformations are apt to vary considerably. Those in the genus *Phytoptus* either make galls upon leaves or secrete themselves in the buds of plants, which then become "puffy" or else contorted and shrivelled. A good deal of notice has been attracted recently to the proceedings of *P. Ribis*, more especially in the case of the Black Currant. Owing to its minuteness and its mode of life the species doubtless passes unseen in many instances.

The Rev. M. J. Berkley, a well-known physiologist, had specimens of a Currant damaged by some *Phytoptus* forwarded to him in 1869, and this seems to have been the first time this particular pest was noticed in England, but several of the gall-producing *Phytopti* had been known years before. A description of the insect and its presumed habits was published by Professor Westwood in the *Gardeners' Chronicle* of that year, and the matter came also before the Committee of the Royal Horticultural Society. Afterwards the species was definitely named *P. Ribis*, although much discussion arose as to whether these *Phytopti* were really distinct species, several naturalists arguing that they were young examples of another group of mites. But these insects have now been examined in all stages of growth and their position established, yet much remains doubtful as to their habits. The young of *P. Ribis* have when very juvenile but one pair of legs; they gradually increase to the number of six, or occasionally eight, some think. These are very bristly, the body is smooth and rather egg-shaped. It is difficult to discern them, even as adults, unless the eye has the aid of a magnifier.

There is ample proof that this mite is lurking within the Currant buds by November, if not earlier. It is, however, during the spring that our attention is called to them, when by their feeding between the young leaflets, abstracting their sap, they effectually stop the development of flowers, leaves, and twigs. As Mr. Andrew Murray remarks, "the buds attacked are seen to languish and decay, or to assume a rounded swollen form without pushing out ('knotted,' some correspondents style it). On tearing open one, hundreds of very small semi-transparent moving things may be seen by a lens. All the surface of the leaflets on which they are scattered has a moist raw-like appearance; in fact, the *Phytopti* have browsed on it until they have flayed it to the quick." Close and severe pruning is the method suggested by this author for the diminishing of their numbers, but he scarcely thinks their extirpation can be thus brought about. Syringing or washing the bushes with one of the many solutions or compounds that are efficacious for the destruction of insects might clear some of them out of the expanding buds in spring, but would not save the buds from dying off. Then the bushes where the mite has been observed might be also syringed in the autumn, since there may then be a migration from bud to bud. It seems to be most frequent in the northern division of this island, where we have seen many bushes attacked, and some ruined. It may, however, be present also in the south. Bushes infested with this destructive mite should never be propagated from. Young trees should be procured that are perfectly clean and healthy, and be planted as far distant as possible from those affected. We have seen perfectly healthy bushes and others seriously knotted in plantations less than 30 yards apart, and we have cut down affected bushes entirely, burning the branches, the resulting growths from the "stumps" of the decapitated trees being quite free from the pest; but if the mite exists on one plant it soon spreads through a plantation.

Fig. 32 (page 165), for which we are indebted to the courtesy of the Editor of the *Gardeners' Chronicle*, represents in the left-hand figure the bud highly magnified, with the outer scales partially opened, showing a few of the mites, which on an average are individually not more than 1-200th of an inch in length. The centre figure represents one of the insects very highly magnified, as seen when crawling along, the right-hand figure representing a very young example lying on its side in a state of inactivity.

If any of our readers have succeeded in extirpating this small mite, yet great Currant enemy, they will do good service by making their method known.]

SEED TIME.

FROM the steady continuance of mild weather it is probable that we shall be favoured with a forward spring, and among the many matters pressing upon our attention at that busy season of the year none is more important than the timely and careful sowing of vegetable and flower seeds. Seed time, in point of fact, has already begun, for are not our first crops of Peas and Beans already "up" and growing freely? and are we not turning up every patch of soil in the kitchen garden in readiness for the general sowing of crops that are soon to follow? For the first spring crops all heavy tenacious soil should have been broken up roughly last autumn; but soils differ much, and well would it be for gardeners if a common standard of excellence could be adopted for all garden soils, whereby they could be brought into such an open friable condition as to be always ready for the seed. Impossible, do you say? Well, I cannot agree with you,

for I can point to a soil, once unfit for the cultivation of any vegetables now in superb condition for the growth of flowers, fruit, or vegetables. Thorough drainage, followed by trenching and repeated dressings of farmyard manure, coal ashes, lime, and decayed vegetable matter, has wrought the change, and it would be difficult to find among soils a greater contrast than is here presented by the soil in its natural and cultivated condition. Let no one suppose the process of soil-improvement is easy, however simple it may be, and that it is simple I am free to own, but it can only be done thoroughly by dint of downright hard work and unflagging perseverance year after year. My first trial crops in the virgin soil of Mid-Sussex were all failures. Even Horseradish refused to grow, Peas only grew a few inches high, and then died, and the soil settled down again with the first heavy shower into a compact mass, so hard that it had to be thrown up in huge clods with spades, and then watered and beat with Canterbury hoe, to get it to pieces. I mention this to show that I have no occasion to draw upon the imagination for an illustration.

What, it may be asked, has all this to do with seed-sowing? Very much, for without a good seed bed failure is very probable. A prompt and unbroken succession of seasonable vegetables is imperative. But how can this be achieved, when weeks of precious time are lost in waiting for a heavy sodden soil to become dry enough for the seed drills? It is high time that it should cease to be possible for it to be said of any garden soil that it is unfit for this or that crop, or that owing to unfavourable weather seed could not be sown. Surely the comparatively small portion of an estate that is required for the cultivation of vegetables might be brought into a suitable condition for the purpose if the urgent necessity for it were only understood by the owner of the garden. Unfortunately matters do not always work smoothly between gardeners and other heads of departments, and then difficulties arise about manure and other things, and many an earnest man finds his efforts crippled and often rendered futile for want of ways and means in the preparation of the soil. Personally I have no feeling in the matter, for as manager of an estate the garden with me is only a department, which it is my duty to see well cared for; but having repeatedly met with cases where the garden was impoverished and the gardener disheartened simply because obstacles existed which he appeared unable to overcome, I would urge upon the attention of employers that it is clearly to their interest that all reasonable requests for materials or labour in the improvement of the soil should be complied with. May I also venture to ask my brother blue aprons, especially the younger ones who have recently risen to responsible posts, to bear in mind that, however clever a man may be, he is unlikely to be fully successful in his calling if he lacks discretion, judgment, courtesy, and tact in his intercourse with others? What matters the swallowing of a slice or two of humble pie if that and a little forbearance enable you to gain your end?

Given, then, good soil, let us take especial care to obtain seed from a safe source, and never be tempted by bargains in seeds. Good seeds true to name, suitable soil, and skilful timely culture are our three indispensables here. In sowing, especially the earlier crops, we must be guided in some degree by weather. In a cold wet spring a little waiting before sowing often proves a saving of time rather than a loss, the warmer drier soil at the later sowing insuring a quick germination of the seed and a free vigorous growth in the plants that well repays for the exercise of a little patience. Do not forget that from the moment seed enters the soil it is liable to the attacks of mice and birds. In walled gardens mice can be kept under, but without walls this is impossible. Of all means of protection there is nothing like sheets of glass laid flat upon the soil immediately after sowing the seed, and kept there till the seedlings are visible, when it is replaced by netting if there is any risk of birds attacking the plants. Thus far we can protect seed and seedlings with certainty from day and night enemies; but now comes the risk of damage from slugs and snails, very few of which are visible by day, but after darkness falls these "demons of the night" are soon busy at the work of destruction, and a few visits to the seed beds with a lamp enable us to catch most of them. Very thin seeding or early transplantation is most important for all plants raised in nursery beds, or they soon become drawn into a slender attenuated growth, which no subsequent care will improve.

The bulk of winter Greens and Broccoli are sown and transplanted before hot weather sets in, and ordinary care is sufficient; but in the heat of summer transplantation is attended with some risk, and I have frequently found it answer well to prick seedlings of succession crops of Lettuce and Cauliflower singly into flower pots holding a trowelful of soil, so that the plants may be placed in partial shade and eventually be turned out into the beds with such a ball of roots as insures to the plants full power to continue growing freely and to become established in the soil quickly. To avoid the attendant risks of transplantation in very hot dry weather seed is sometimes sown thinly in the rows, and all superfluous plants after-

wards pulled up and thrown away; but this is a wasteful process, which also involves much extra watering.

One word more about seed-sowing in pots. About most seeds so sown there is no difficulty. It is only very fine seeds, such as Gloxinias and Begonias, that so frequently come to nought, simply because so many will persist in sowing on peat, which dries quickly, and is not easily saturated again even by standing the pots in water. Avoid peat for this purpose, and sow on compost consisting of very old decayed vegetable matter, such as all gardens afford a supply of, with fine grit and wood ashes thoroughly mixed and passed through a very fine sieve. Let the soil be well watered before sowing, lay pieces of frosted or whitewashed glass upon the tops of the pots, and the seedlings will usually be visible before more water is required.—EDWARD LUCKHURST.

THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

IN your report (page 125) of the annual meeting of this Society, in the member's private balance sheet, of which you gave a copy correctly, there is an error in the figures. I had on the debtor side placed the figure 2 in the wrong column. Perceiving my mistake, with my pen I made a slight dash over it, but not sufficient to obscure it from the printer's notice; so in the deduction for sick pay it reads £2 2s. 6½d., whereas it should only be 2s. 6½d. The amount for the one year's sickness was deducted from the members' contribution as follows: Forty-three members would receive 16s. per week each in sickness; them I charged 2s. 6½d. each, amounting in the whole to £5 9s. 3½d. Fifty-seven members receiving 10s. 6d. per week each I charged 1s. 7d. each, amounting

Fig. 32.—Phytomyza Ribis (see page 164).

in the whole to £4 10s. 3d., the total being £9 19s. 6½d. The number of members who received this pay was two—one, a member of long standing, £1 11s. 6d.; the other had just completed paying his first year's subscription, which entitled him to the Society benefits when he became sick, and received in the whole £8 8s. I shall receive shortly from the printer the public balance sheet, with list of members and their addresses, &c., which I will forward with the rules to those who have applied for them through reading the said report.—J. F. McELROY Secretary.

USEFUL PLANTS.

POINSETTIA PULCHERRIMA PLENISSIMA.—A very useful plant, and when treated to the liberal treatment usually given to the single form makes a good succession to that. My experience with this double Poinsettia goes to prove that it is capable of lasting a much longer time in bloom than the single one. Some I have known to say of this plant that it is no use as compared with the old form, to which I reply, "Then grow it for ornament," which it certainly is if well cared for after the "old form" is over.

SPARMANNIA AFRICANA.—Another useful plant flowering just now, and helping greatly to fill up the gap caused by the removal of the Chrysanthemums from the conservatory. In a large state this plant is well adapted for grouping with other plants of a dwarf nature; it is also very pretty in small pots. Cuttings inserted in large 60's shortly will make good plants by the autumn.

ECHEVERIA RETUSA.—This should be grown everywhere and by everybody, it is the easiest plant to cultivate with which I am acquainted. Cuttings inserted now and grown on in a little heat will make useful plants for filling up the centres of flower beds if wanted for that purpose, and if not they should be planted out in the open ground in well-prepared

soil, and attended to during the summer. They must be carefully potted, and should not be overwatered, or the lower leaves will damp.—G. MERRITT.

FLOWERS BY PARCEL POST.—The Postmaster-General has issued the following notice:—"The season is now approaching when, according to a very general custom, Primroses, Violets, and wild flowers of all kinds are entrusted to the Post for transmission between places within the United Kingdom. As the Parcel Post may be extensively used for this purpose, the attention of the public is drawn to the expediency of properly securing the parcels so sent. The box in which flowers may, in each case, be contained should be of a material so much stronger than cardboard as to bear pressure and friction in transit. Cardboard boxes are frequently reduced to pulp by moisture from freshly cut flowers or wet moss soaking through them, and are, therefore, not suitable."

— IN addition to the sums received during the week for MRS. HONEYMAN, and acknowledged by post, Mr. Wright has great pleasure in recording the receipt of £2 17s. 6d. as the result of a subscription amongst the young men in the Royal Gardens, Kew. The subscription list numbers thirty-four names, and was, with the sum named, forwarded by Mr. W. Harrow. The thoughtful action of the Kew students is much appreciated. "W. B., Rothbury," has also sent a further subscription of 18s. from a "few friends." Will he please state the name in which the Post-office Order is taken? Mr. Wright has now received the amount he hoped for, and although any further sums that may arrive will be thankfully accepted, no further appeal is made to the kindness of readers of this Journal.

— QUITE a concourse of Orchid growers assembled at Messrs. Protheroe & Morris's rooms, Cheapside, on Tuesday last, to witness or participate in the monthly SALE OF ORCHIDS IN FLOWER. About four hundred lots were offered, including large numbers of Cattleyas, some very handsome plants; Dendrobiums, Odontoglossums, Angre-cums, and miscellaneous species, which afforded a grand display of flowers. An exhibition such as this is rarely seen in a sale-room, and it is not surprising that it attracted so large a number of visitors. The prices realised were generally good, a beautiful example of Cattleya Warscewiczii delicata with thirty pseudo-bulbs and a dozen expanded flowers being sold for nine guineas, and other fine varieties at proportionate prices.

— RELATIVE to CLEANSING VINE RODS, "A. M." writes:—"At page 90, in the issue for Jan. 31st, 'Ipswich,' in reply to Mr. Iggulden, states that he applies his wash to the Vine rods in the same way as a groom applies water to the spokes of a carriage wheel. That would be with a spoke-brush; but as I cannot think he uses a spoke-brush to his Vines, with what does he apply it? and how does he keep it at the required temperature?"

— WE have still more about CHOU DE BURGHLEY. From a child it has become a parent. We had better, however, publish a characteristic note pertaining thereto.

"Don't look at me and my Chou with a frown. My only object is to put down prejudice. I therefore send you, so that you may for yourself see, that every other green in our garden is run to seed and useless, while Chou de Burghley and my new Savoy are the only things we have for use until the spring Cabbage comes in, and that won't be until April. Another thing I may tell you is they never crack, while others do badly. The new Savoy, Gilbert's Universal, the result of a cross between Chou de Burghley and an ordinary Savoy, is perfectly selected and a 'topper.'—R. GILBERT."

— THE specimens referred to—Savoys, Brussels Sprouts, Colewort, and Scotch Kale—are producing flower stems. "Chou" and the new Savoy show not the slightest signs of moving in that direction. The latter is round, about the size of a cricket ball, the heart being of the same pale green colour as Chou de Burghley, the outer leaves resembling those of Brussels Sprouts more than Savoys. The example before us is quite distinct from anything we have seen, and its lateness in comparison with the others referred to undoubted.

— MR. GILBERT also sends a charming bouquet of delightfully perfumed and very large, double, white, fringed Primulas, with handsome trusses of the large, single, creamy-white Polyanthus or BUNCH PRIMROSE HARBINGER, similar examples of which would adorn any greenhouse or conservatory in the land. The variety is, we are aware, quite hardy, but we cannot imagine that such flowers as those before us could be produced without the shelter of glass.

— "T." writes:—"In my remarks upon GALANTHUS ELWESII, page 148, by some mishap the segments of the perianth are described as 'brown' instead of 'broad,' as I need hardly say no Snowdrop has yet reached us with brown perianth divisions."

— THE CARLISLE AND BORDER COUNTIES HORTICULTURAL SOCIETY have issued their schedule of classes and prizes, which gives the date of the Summer Show, to be held in Major Binning's field, Chatsworth Square, Carlisle, as July 17th and 18th. The prizes are mostly of small amount, but the classes are numerous, ninety-nine being enumerated for all kinds of garden produce.

— ORCHID SALES were numerous last week, no less than four having been held, two each at Mr. J. C. Stevens' rooms, King Street, Covent Garden, and Messrs. Protheroe & Morris's rooms, Cheapside. These were nearly all imported Orchids, and the frequent large consignments of Orchids now sent to this country prove that the demand continues unabated. The sales are well attended by the trade representatives and amateur Orchid growers, the competition for any desirable novelty being often very keen, resulting in corresponding high prices for the vendors. Improved varieties in flower of such Orchids as Odontoglossum Alexandræ and others of a similar character realise, however, the highest prices, and often there is sufficient incredulosity respecting imported novelties, of which the flowers have not been seen in this country, to keep the prices rather low. This was seen in the case of Aerides Rohaneana, of which some of the largest pieces were unsold, and the highest bids obtained for others were twelve or fourteen guineas.

— MR. F. W. BURBIDGE, Trinity College Botanic Garden, Dublin, sends the following note on PLANTS IN FLOWER:—"The little Pinguicula hirtiflora from Italy is now flowering here, also P. caudata from Mexico, and the Sulphur Hooped Petticoat Narcissus (Bulbocodium citrinum) is lovely with seven or eight flowers; N. Horsfieldii, N. princeps, N. obvallaris, and others are also now most beautiful in pots, as also is the old King's Signet or Solomon's Seal forced in a little heat, each long arching stem of soft green leaves now being strung with soft pearly blossoms. Primula obconica in a cool greenhouse, and Impatiens Sultani in a stove, have never ceased flowering for the past fifteen months. The Balsam cuttings even keep on flowering as they are rooting in the propagating pit, and we think it prettier in a small state."

— A PAPER on the average rainfall of the last ten years IN THE ATLANTIC PORTION OF THE UNITED STATES has appeared from the Signal Service Department at Washington, which gives the following interesting particulars:—"Our rains come from the vapour which rises under the warm suns over the Gulf of Mexico. The ice of the north prepares a cold heavy current, which, rolling down towards the lighter column of the Gulf, draws the lighter northward to fill the vacuum. As the colder meets the warmer rain is precipitated, and this would be exactly the same if there were not a tree on the whole Atlantic coast. These show that notwithstanding the awful destruction of the forests of which the newspapers and some magazines tell us, the rainfall of the past ten years is just the same as that of the ten years previous. It is the diminution of the ice towards the pole that we have to fear, rather than the diminution of the forests, when we calculate on our country becoming an 'arid treeless waste.'"

— PARTS 41 and 42 of PAXTON'S FLOWER GARDEN (Cassell and Co.) contain coloured plates of the following plants:—Billbergia Moreliana, a handsome Bromeliad, with long striped leaves and a large drooping panicle of blue and red flowers; Gesnera purpurea, with long tubular flowers borne in a loose panicle, purplish red dotted with scarlet; Cymbidium Mastersii, a species from the East Indies, with narrow white petals and a lip faintly tinged with pink; and Billbergia thyrsoidea, a very distinct and noble species, with a massive dense conical or thyrse-like head of rosy crimson flowers and bracts. In the gleanings and memoranda woodcuts of Begonia Martiana, Acacia cochlearis, Nicotiana alata, a species very nearly resembling N. affinis, Coreopsis filifolia, Chænostoma linifolium, Grindelia grandiflora, Calceolaria stricta, and Nymphæa scutifolia.

— "G. H. R." requests the insertion of the following question:—"Can any correspondent inform me the best way to get rid of slugs on outside Mushroom beds otherwise than picking them off by hand?"

— AT a recent monthly meeting of the NORTH OF SCOTLAND HORTICULTURAL ASSOCIATION in Aberdeen, Mr. J. Sim delivered a very interesting lecture on the Strawberry, in the course of which he remarked that the varieties grown in America have peculiar characteristics not common to British Strawberries, and he thought many of them should have a fair trial in this country. With reference to recent remarks by Mr. Gladstone on fruit-growing, he (the lecturer) considered it an industry more fitted for owners of the soil than for tenants, as two years' notice to quit would be required for any kind of fruit-growing, and five or six years for some descriptions. Large quantities of Strawberries are sent out from Aberdeen to other parts of Scotland, and to England and Ireland.

— GARDENING APPOINTMENT.—The following appointment has been made through Messrs. John Laing & Co., Forest Hill:—Mr. Ch. Fowell, late foreman to the Duke of Grafton, Euston Hall, as gardener to Ed. A. Ball, Esq., Rolls Park, Chigwell, Essex.

— A CORRESPONDENT writing respecting the EDINBURGH SHOWS in 1884, observes that "The Royal Caledonian Horticultural Society are to be congratulated on their arrangements for 1884. As an ordinary prize list theirs is the best I have seen issued. The total amount of £876 is offered in prizes. Well done, Edinburgh! It will no doubt be the ardent hope of every horticulturist that this substantial inducement to produce fruits, flowers, and vegetables of the highest quality will meet with the reward it so well merits. Collectively more is given in Edinburgh for vegetables than is offered at the Dundee International, and I am very glad to see that at each of the Edinburgh Shows vegetables will be well represented. In fact, I cannot understand the way this leading International of 1884 has ignored our kitchen garden produce. The newly introduced prizes for honey is an excellent addition to the Edinburgh list, and I hope to see many other societies follow their example."

— THE Paris correspondent of the *Daily News* remarks that "eaters of TRUFFLES, esteemed the greatest of French delicacies, are now terrorised by an extraordinary panic. It is familiar knowledge that they are often adulterated in various ways. It is hard to believe that lozenges of black cloth garnishing the cuticle of a turkey can be passed off as Truffles to any great extent, but harmless blackened bread crumbs, potato, and Turkish flour are often fraudulently introduced into the jackets of the Perigord black Potato, and are eaten with perhaps the remark that the Truffles of the year are wanting in perfume. Now it is alleged that ten general officers were taken very ill after eating Truffles at a Palais Royal banquet. The police have arrested a man who they say had a great manufactory of false Truffles at Versailles, and obtained the right perfume by means of an essence of a highly deleterious character. He awaits his trial, and meanwhile orders have been given to visit all shops and market stalls where Truffles are sold, and bring specimens for analysis to the municipal laboratory."

— THE GLASGOW AND WEST OF SCOTLAND HORTICULTURAL SOCIETY announce that their Shows for the present year will be held on March 26th and September 3rd, both in the City Hall, Candleriggs. At the first sixty-five classes are provided, the prizes amounting to £73 12s. 6d.; at the other 140 classes are enumerated, and the prize money £185 1s.

— THE monthly general meeting of the NOTTS HORTICULTURAL AND BOTANICAL SOCIETY was held at the Mechanics' Institute, Nottingham, on Thursday evening, the 21st inst., when Mr. J. H. Walker of Hardwick House Gardens, Nottingham, read a very interesting and exhaustive paper on "Mushrooms and Mushroom-growing." There was a crowded attendance of gardeners and others interested in horticulture. Mr. Chas. E. Pearson of Chilwell Nurseries occupied the chair. There were upon the table some splendid flowering Orchids, sent by Mr. Meadows, gardener to J. C. Cox, Esq., Basford, amongst them being a remarkably fine plant of *Odontoglossum Rossi* var. *majus*, carrying over eighty fully expanded flowers, and which was awarded the Society's certificate of merit. The same exhibitor had also a very highly coloured variety of *Dendrobium* "maxillare" (?) which was much admired. Samuel Thacker, Esq., the Vice-President, sent six fine forms of *Dendrobium* nobile and cut blooms of *Anthurium Andreanum*. Messrs. S. & T. Bar-

ratt of Rateliff-on-Trent had splendid bunches of the pretty *Clematis indivisa lobata* covered with its beautiful flowers.

— IN the paper on MUSHROOM-GROWING above noted Mr. J. H. Walker spoke of the possibility of distinguishing edible from poisonous Fungi, and said there was only one way in which the test could be applied with absolute certainty—namely, that by bringing to bear a thorough knowledge of the individual species and the situations in which they were grown. It was upon the so-called common Mushrooms that he wished to speak. The growth of these in their wild state was very uncertain, large quantities being found in one season where few or none were found in the previous year. Having stated that he had no doubt situation had a great deal to do with the nutrition as well as with the poisonous qualities of the Fungi, Mr. Walker observed, as a curious fact, that the common Mushroom (*Agaricus campestris*), which was so much eaten and esteemed in England, was prohibited from being sold in the public markets of Rome on account of its poisonous qualities, and he said he could himself testify to the fact of a fellow workman having been made seriously ill on two occasions through eating Mushrooms which were grown in close proximity to stagnant water. Having referred to the means of cultivation in vogue in Italy, Austria, and France, and mentioned that it was estimated that the value of Mushrooms grown in Paris alone last year amounted to over £89,000, the lecturer said Mushroom-growing in England had now become so simple that it was well worthy the attention of those who were engaged in agriculture and in horticultural pursuits, as the fact could not be overlooked that the continuous increase of the population would eventually demand a free development of the resources of the country. For this reason Mr. Walker expressed his opinion that the Mushroom would in the future occupy a most important place in the dietary of the English nation, and he then mentioned what in his opinion were some of the chief points connected with the indoor cultivation of the edible Fungus. A short discussion followed, and some questions were put to Mr. Walker, who replied to them. In the course of the discussion one speaker said he knew a person living in the neighbourhood of London who last year realised as much as £950 from Mushroom-growing, and who hoped this year to clear £2000 from this source.

— WITH regard to the notice of the meeting of the Notts Horticultural Society (page 109), it may be stated that a prize of £1 was offered for the best report sent to the horticultural papers. This was awarded to our correspondent Mr. N. H. Pownall, who worthily proposes, with the consent of the Committee, to re-offer it as two prizes of 10s. each to under-gardener members of the Society for the best two papers upon "THE ROTATION OF CROPS IN A KITCHEN GARDEN," to be illustrated by a plan, and not to exceed twenty minutes in reading. The subject will be very instructive and useful.

— THE INTERNATIONAL FORESTRY EXHIBITION, which will be opened in Edinburgh on 1st July next, is intended to include everything connected with, or illustrative of, the forest products of the world, and will be open to exhibitors from all countries. Applications for space must be sent in before 31st March. The Committee will endeavour to obtain from the various British railway companies special terms for the conveyance of exhibits to and from the Exhibition. Medals, money prizes, and diplomas for exhibits and essays will be awarded by competent jurors. Contributors to the Loan department are requested to communicate with the Secretary, who will supply special forms to be filled up by them. Free space will be given for workmen's approved models. Specimens will be shown of the various kinds of axes used for felling trees, as also of the different descriptions of machines for preparing the timber for constructive purposes. There will also be on view examples of textile fabrics manufactured from bark. The literature of the subject will be illustrated by reports of the schools of forestry in all parts of the world. Closely allied to this branch of the subject is the preparation of working plans, showing the age of plantations and the stage of growth at which cutting should be resorted to. The Loan collection of the Exhibition will, it is anticipated, prove one of the most attractive of all, including notable specimens of carving, wood-engraving, photographs, paintings of famous trees, and also sporting trophies from all parts of the world. Her Majesty has graciously consented to allow her name to be placed on the list of patrons, an example which has been followed by their Royal Highnesses the Prince of Wales, the Dukes of Edinburgh, Connaught, Albany, and Cambridge. The Lords of the Committee of Council on Education have been pleased very warmly to

commend the project, as likely to foster and encourage the spread of the knowledge of scientific forestry, and Her Majesty's principal Secretaries of State have accorded to it their hearty recognition and support. The Commissioners of Woods, the War Department, and the India Office propose to be exhibitors, and a consignment of colonial timber has already been forwarded from the Royal Gardens, Kew. As usual in such undertakings, a guarantee fund, which at the present date amounts to over £6000, has been started to insure the promoters against loss. The Executive Committee consists of the Marquis of Lothian, K.T., President; Sir James Gibson-Craig, Bart, Vice-President; the Lord Provost of Edinburgh; Mr. Hutchison of Carlisle; Dr. Cleghorn of Stravithie; Mr. Murray of the *Challenger* expedition; Mr. Skinner, City Clerk; Mr. F. N. Menzies, Secretary of the Highland Society; Mr. Dunn, Dalkeith Gardens; Mr. Methven, nurseryman; Mr. Park, engineer; Mr. Wenley, Bank of Scotland. Of these gentlemen, Messrs. Hutchison, Menzies, Cleghorn, and Skinner act as Honorary Secretaries; Mr. Wenley as Honorary Treasurer; and Mr. Cadell, formerly in the Indian Forest Department, has been appointed Secretary. The Offices are at 3, George IV. Bridge, Edinburgh.

ROSE MARECHAL NIEL.

THIS superb Rose is well worthy of the extended cultivation which it receives, and with the exception, perhaps, of the good old Gloire I know of none that so well repays the efforts of the cultivator, its great drawback being the shortness of its display of flowers, but during the flowering period I know nothing to equal it in beauty. I know a knotty cracked old specimen that last year yielded over a thousand flowers, and that with little trouble. Where the plant obtains its nourishment is somewhat of a mystery, as it is growing in an 8-inch pot plunged in a border about 2 feet wide, and none of its roots have been observed in the border outside the pot. If they have gone down perpendicularly after leaving the pot they must have found a rich feeding ground somewhere. It is budded on the Briar about 3 feet above the ground. This Rose well repays for cultivation in pots for early forcing, and that cultivation is remarkably easy. Whatever may be the case with some Roses this Rose grows and flowers as well on its own as on foster roots, and strikes as freely as a *Pelargonium*. Cuttings, which may be had in plenty as the plant ceases flowering, are best inserted singly in thumb pots, using good sandy soil and leaf mould or Mushroom-bed refuse. Place them quickly in a propagating frame in good heat. Bottom heat may be an advantage: it is not indispensable, and they will root in a month or five weeks, or some in less. I have had some rooted in three weeks, and others of the same batch have taken twice that time. When rooted they are taken out of the frame and transferred into 4½-inch pots as the small pots become full of roots; and here I may say that if any do not grow freely at this stage they had better be thrown away, as time spent in coddling a weakly plant is wasted. Employ a compost of sound loam with sand and decomposed manure. From the 4½-inch pots they may be transferred into 7-inch, using a good compost, and in these they may be allowed to remain till after flowering.

Our plants are kept in heat trained up the back wall of a lean-to Cucumber house till the roots have taken to the soil in the larger pots, when they are removed to the greenhouse and trained up the rafters, and with careful attention grow to the length of 9 or 10 feet by autumn, and after being rested and nailed to a south wall they can be readily forced. If bent down in the same way as young Vines every bud will start. After flowering they may be transferred to larger pots 10 or 12 inches in diameter, and in these they will grow well for several seasons if judiciously fed after the pots are full of roots. I have a large plant which has grown nearly three years in a tub that holds little more than a cubic foot of soil, and for the last twelve months or more this tub has been crammed with roots; yet the plant made several shoots last season varying in length from 5 to 10 feet and stout in proportion, beside a host of others of less dimensions, but all useful for producing flowers. All the assistance this plant had was a potful of weak liquid manure once a week.

This Rose does not seem difficult to suit in the matter of soil. Two of the most vigorous young plants I ever saw are growing in widely different composts. One is growing in a tub about 2 feet square by 1 foot deep, and was planted in sods freshly cut; the other is growing in mixture of clay and decayed garden refuse. Both are on their own roots and about the same age, and there is little to choose between them. I think that plants on own roots are nearly as liable to crack as worked

plants. I know two valuable specimens that commenced to crack in the main stem about 3 feet above ground. As soon as the crack was observed a box supported on stakes was placed round it and filled with good soil. Roots soon began to appear at the cracked part of the stem, and when the box was full the main stem was severed and the whole plant lowered till the box rested on the ground, when it was knocked away from the ball, which was planted in good soil, and the plant soon grew away as freely as ever. If the crack is situated so that boxing cannot be done, and the stem below is bare of shoots, a few buds may be inserted, and when they have taken the stem may be cut below the crack, which will cause them to start, and if the root is sound a good plant will soon be had. If there is a healthy young shoot below the crack it might be inarched into the stem above the faulty part, and a supply of sap again established. This mode of renewing the cracked stem of a fruit tree is successful, and I see no reason why it should not be applied to the Rose, but I have not tried it.

Some growers prune this Rose severely after flowering, some going to the length of cutting all growth back to three or four buds from the main stems. By this method strong growths are obtained, but the flowering capacity is lessened, as flowers are freely produced on the shorter growths which spring from last year's wood. I believe the only pruning needed is thinning out the weak growths as the plant becomes crowded. Bending down the strong growths as much as possible when growth has ceased for the season has the effect of causing every bud to break into flower in the coming spring, and also of sending strong growths out from the base of last year's wood, thus securing all the advantages of close pruning without its attendant sacrifice of valuable flowering wood. I believe it is necessary to bend down the wood early in winter, as I have never had such a regular break when it has been deferred till growth has nearly begun.—T. A. B.

FRUIT-TREE CANKER AND ITS CAUSES.

I SUSPECT that very few practical gardeners will accept the dictum of Mr. Hiam, on page 132, that the insects he found in the cankered portions of the Apple trees were the cause of the canker. There can be no doubt of the presence of the insects. They are found in all decaying vegetable matter quite regardless of the cause of its decay. One of the worst examples of canker I ever had to contend with was a Hawthorn Apple tree, not very old, but a very favourite specimen. This tree was also attacked with American blight, and was regularly dressed with Gishurst compound, and eventually with methylated spirits, until the insects were killed; but still the cankering of the branches continued on the old and young wood alike. The tree was taken up and replanted in good soil and the roots kept near the surface, the result of which was better growth and good fruit; but very severe winters following, the thermometer registering below zero, the canker became as bad as ever. In this case I am convinced the frost destroyed the tissue of the wood, and the inevitable result was gangrened branches. After the severe winters of three or four years ago I observed thousands of cases of canker on Apple trees that were previously free; and I am obliged to believe that if insects caused the canker they were brought by the severity of the winters. Does anyone believe that such was the case?—A YORKSHIRE GARDENER.

WITH regard to the notes published on page 132, tending to show that canker is due to insect agency, I have an impression that soil has, if not everything, at least very much to do with this annoying disease. I have it appearing on Apple trees less than two years from the bud, and young trees three to five years old are in some kinds subject to a form of canker that destroys them entirely. This is different from the canker attacking aged trees. I am inclined to believe that were we to keep the soil firm and the roots near to the surface we would hear less of canker. Then wet and frost has a tendency to bring on, or at least to exaggerate the disease, as we have found from the past severe season. As to Apricots, Mr. Crossling wrote of the larvæ of the Apple Clearwing destroying the branches of these. I have found the caterpillar at work in autumn, but am impressed with the belief that their feeding ground is in the already dead portion of the stem. At the present time I have been destroying caterpillars working between the dead bark and the cankered wood of the Apricot. Woodlice are quite commonly found in the same quarters. The form of Apricot canker which destroys large branches has done its work before the damage is apparent. Another form of the disease cuts off strong-growing branches, this through the rupture of the sap vessels. Cold easterly winds and hot days intervening I am afraid mean something not to the benefit of Apricots. I have been so impressed with the advantages of keeping the soil firm for fruit culture, that neither Currant, Raspberry, nor Gooseberry quarters are now being dug here. I intend to try Apples under the same conditions.—R. P. B.

READING Mr. Hiam's notes on the above subject in the Journal of the 14th of February, I should like to add a few words. I have tried to ascertain the cause of canker, and failed so far, our trees suffering much from it in this district. Undrained soil is not the

cause. I find Ribston Pippin as bad on light loam with a dry sandy subsoil as on gravel, and worse on well-drained land than it is on stiff loam with a clay subsoil. It is not caused by climatic changes, being quite as bad in mild winters and springs as in severe weather.

I do not think insects are the cause of the disease. A Pearmain tree is badly cankered in the stem on one side only, a portion of the bark about the size of one's open hand being eaten away; the rest of the bark, about two-thirds round, is, to all appearance, healthy, and supplying the tree with what nourishment it receives, the wood being dead right through to the living bark; it has been so for years. If insects are the cause, would they not have gone completely round the branch and killed it instead of commencing again higher in the same tree? As regards insects showing a preference for the best-flavoured sap, with us the Wellington is nearly as bad as the Ribston, and if the sap is flavoured anything like the fruit of the former I do not admire their taste. I mean to give Mr. Hiam's remedy a trial, and hope it will succeed, having been in search of a cure for a long time.

I have tried grafting healthy stocks and transplanting them every two years, keeping the roots pruned to prevent them reaching the subsoil, but canker occurs even then.—H. E. M.

ELECTION OF CARNATIONS AND PICOTEEES.

THE ELECTORS' RETURNS.

[The names of the raisers of the varieties in the following lists have been given in the previous returns.]

From Mr. JON. BOOTH, Failsworth, Manchester.

CARNATIONS.

Scarlet Bizarres.

Admiral Curzon
Dreadnought
Mercury
Robert Lord
Edward Adams
William Spoor

Crimson Bizarres.

Master Fred
Lord Milton
Eccentric Jack
Graceless Tom
E. S. Dodwell
Jenny Lind

Pink and Purple Bizarres.

Falconbridge
Sarah Payne
Mrs. Anstiss
H. K. Mayor
James Taylor
Squire Llewelyn

Purple Flakes.

HINTS ON SOILS AND POTTING.

THE season has again arrived when potting plants is generally commenced, though I think that annual repottings in spring are not so much followed now as formerly. It is not, perhaps, desirable to enter too minutely into the details connected with potting plants. Hard-and-fast rules are quite as inapplicable to this phase of gardening as to any other; therefore it may be of more general service to state some of the main points in connection with the subject. It may be stated that many plants requiring annual or biennial repotting are best attended to in the early part of September or even earlier in autumn. Plants repotted at that season are established before winter, and more ready for a start in spring than if repotted at the latter season. But even when the system of autumn potting is carried out there still remain many plants to be attended to now. It will be a more convenient way to treat this subject by dividing it into two sections, first describing the soils and then the manner of potting.

SOILS.—Gardeners, and amateurs also, have much to depend on local surroundings for potting material. In my case for several years the best soil I could command was obtained from an old rubbish heap. I am glad to say that a more suitable material is given me now; but in the matter of peat soil, unless it is bought at a heavy rate, there is nothing fit to use in our locality. Most people who own a garden are more or less fond of it and its products; but not many like to purchase either turf or peat at the ordinary prices, and a gardener is much left to his own devices. I have proved that many plants will do fairly well in very ordinary material, provided it has not a tendency to become clogged and sour. The main safeguard against these evils when fibreless or clayey soils have to be employed is to make use of the smallest pots possible consistent with the size of the plants.

Another way I have seen tried, but which I do not follow myself and therefore do not recommend, and that is to mix a large proportion of rough leaf soil, rough dung, and sand with the soil and pot rather loosely. Such mixtures invariably become sodden after a lengthened period in use, and the quality of the roots formed even in its best condition readily decay. The quality of growth is also deficient in that firmness of quality so necessary to insure continued healthiness. As a rule, I hesitate to employ leaf soil and decayed manure in conjunction for any plants, and would only do so for those required to make a very rapid growth, and which are likely to be thrown away after that growth had been finished. The only manures I use are half-dried cow manure in a condition to rub down into fine flakes, and horse droppings prepared as for growing Mushrooms. Sheep manure in a half-dried condition is also suitable.

Though I am able to get plenty of good turf for potting, I do not use that for every plant. Turf has the one fault of being too quickly exhausted in the case of plants which have to grow in one pot and continue flowering for a long time. For instance, we employ no turf for Chrysanthemums, winter-flowering Pelargoniums, nor Carnations. These do much better, though the growth is not so strong, in fibreless loam with a good proportion of cow manure added. When sand can be dispensed with it is also better omitted. I seldom use it. Doubtless roots are more freely produced where open sandy composts are used, but a compost in which roots are formed in moderate proportional number with the top growth is much better than using one which is too rapidly taken possession of by the roots and at once exhausted. These open composts are the worst for holding applied manures. I have occasionally bloomed winter-flowering Pelargoniums, which were potted in the summer, from

October through the winter and spring on to the next October with the aid of occasional surfacings of fertilisers. Last autumn one of the cottagers here showed two plants 3 feet across and covered with trusses, which had flowered in our hothouses all the winter and were given to him in spring, and which he kept in the same 6-inch pots.

A compost the most conducive to rapid growth is one formed of turfy loam and good fibrous peat. For growing rapidly into specimens such plants as Ferns, Tea Roses, many stove and greenhouse plants, nothing can be better than the above. When fibrous peat cannot be obtained the roots of such vigorous-growing Ferns such as *Lastrea dilatata* or *L. Filix-femina* are very suitable. For mixing with composts for many plants crushed lime rubbish is better than sand. Bones are a very good fertiliser, and the best form to employ that in is as bonemeal. Crushed bones and half-inch bones do not act so quickly; and although roots may be found clinging to these, that is more a proof of their being conservative of moisture than that the plants are deriving food from them in any quantity. Pure leaf mould I use for many plants that are to be grown only a short time in pots and then turned out—such, for instance, as bedding plants and ordinary Dahlias. Amateurs are often fond of experimenting, and one showed me last spring some good *Calceolarias* thriving in ordinary moss lifted from the base of a forest tree. Sphagnum is a very good substitute for peat for potting stove plants. *Alocasias*, *Anthuriums*, and plants of that description thrive well in pure sphagnum. Either sheep-droppings or cow manure should be used as surfacing about three times through the growing season.

As a rule it is safest to employ simple composts. It will invariably be found that when a plant has to be a long time in one pot, and to bear therein a crop of fruit, as in the case of Strawberries or Pine Apples, or a continued succession, or a large crop of flowers, as in the case of *Chrysanthemums* or *Pelargoniums* in winter, then a very simple compost is a necessity.

POTTING.—Pots, it may be said, are a necessary evil, though any plant grown in pots may be as well or better, and certainly more cheaply grown in beds or borders. That, however, is not always convenient, and therefore we are compelled to use pots. For the everyday gardener, whether professional or amateur, the great point to be considered with regard to plant-growing in pots is the best means of getting the greatest amount of plant food possible within their very contracted limits. First of all drainage may be mentioned. No rule can be laid down as to how much drainage should be given to a plant. I may merely place a piece of broken pot over the outlet of a 6-inch pot, if I use leaf soil simply; or if the plant is to be only a short time in the pot, as in the case of a Tomato or a Dahlia, but with a Fern, a *Pelargonium*, or a *Primula*, the case is different. Coal cinders are preferable to potsherds for draining most pots, except the very largest sizes usually employed for stove and greenhouse plants. For large pots it is decidedly the best system to give abundant drainage. Of two plants, one in a deeply drained pot, the other with little drainage, the chances are all in favour of the better drained pot producing the healthier plant. The soil ought to be in such a condition that if a portion is squeezed in the hand it will readily crumble into loose soil again at a very slight touch. Dryness is bad, wetness is worse. In the state above indicated as most suitable, it is a safe plan to cram as much of it into a pot as possible. Certainly the growth will not be so luxuriant as if a looser mode of potting were followed, but in the long run it will be found that firm potting followed out as a rule will give the best results. Small pots with firm potting is the simplest and most certain way of laying the foundation of healthy plants. These few principles will be found a sufficient guide for beginners who with a love for their work require a guide to mark their way.—R. P. BROTHERSTON.

VINES BLEEDING.

As far as my experience goes on the above subject I fully believe that Vines which bleed to any great extent are much weakened for the ensuing crop. In the earliest house of Black and Golden Hamburgs here last year's observations convinced me of the above statement. The Vines were pruned in the last week of November, and their age as near as I can guess is ten or twelve years. One Black Hamburg had four strong main rods, and to give them more space we took out the oldest rod of the four, cutting it about 2 inches from the juncture. The diameter was fully 2 inches where it was cut. The Vines were started in the last week of January, all seeming to break the same and make the same progress till they were bursting into leaf, when the Vine under notice showed signs of weakness; but as there was a stage along the front of the house filled with plants the wound was hidden below the stage, as they are planted inside. There was little done to discover the weakness till it was plain that something was

wrong, when it was found that it had been bleeding severely for some time, but I cannot say the date at which bleeding commenced, but it continued its exhausting work for ten or fourteen days after our notice. The result was weak wood and small bunches, about three weeks later in ripening than the others in the same house. It may be also stated that the Vine under notice was at the coolest end of the house, and that might have caused it to be a little later, but it would not have impaired its strength.—J. S.

DIARIES AND BOOKS FOR GARDENERS.

A WELL-KEPT record of the daily work done in gardens, with notes on the results of past work and the condition of plants and crops, is of the greatest importance to both old and young gardeners. There are so many forms of diaries now to choose from that any person can select one to his own particular taste. I prefer to obtain a large foolscap scribbling book containing about 300 pages, and prepare it as follows:—About fifty-two pages are selected at the end of the book; these are marked with the letters of the alphabet in red and blue ink on the margins of the leaves. Two leaves, or four pages, are allowed for each letter. After the first letter "A" is marked a strip is cut off the two pages the width of the letters, and the next letter "B" marked, continuing thus until the whole of the letters of the alphabet are printed. This method is employed for special notes, as for example, "Early Peach house started January 1st, 1884." Now, as "Peach" is the subject referred to, I should place my thumb on the letter "P" on the margin, open the book at that place, and enter the note. By the adoption of this simple method I can refer to notes on any particular subject at a moment's notice without having to wade through the matter in the full and general portion of the diary.

I have two books, one for the farm and one for the garden, and can refer to these as easily as an index to a volume. Then I adopt one page of the garden book to a table of outdoor temperatures. It is arranged in columns thus:—The first column on the left-hand side is for the date of the month; following this are two columns, maximum and minimum, for each month, with the name of the month neatly printed over each pair of columns. The temperatures of the first day in each month are thus given in parallel columns, and so on throughout the year. The preceding pages of the book are devoted to a full description of whatever is done during the day, with observations thereon. It will thus be seen that a diary of this kind is a complete vade mecum of useful and interesting matter. I have kept such a diary for many years, indeed ever since I commenced my gardening career, and have always found it a source of pleasure and profit in doing so.

Having briefly referred to the question of diaries, it may possibly be of service to some of the younger readers of the Journal to name a few books on gardening that have been found useful, and which may soon be obtained by those who do not spend their money in the frivolous customs of life. Amongst other works the following are strongly recommended to form the nucleus of a gardener's library:—Johnson's "Cottage Gardener's Dictionary;" Dr. Hogg's "Fruit Manual;" "Vines at Longleat;" Fawkes' "Horticultural Buildings;" Burbidge's "Cultivated Plants;" Smith's "Ferns: British and Foreign;" Lindley's "Theory and Practice of Horticulture," and "Vegetable Kingdom;" Williams' "Stove and Greenhouse Plants," two vols.; and "Orchid Growers' Manual;" Thompson's "Gardener's Assistant" (new edition); D. Thomson's "Handy Book of Fruit Culture under Glass," and "Handy Book of the Flower Garden;" Veitch's "Manual of Coniferæ;" "The Farmer's and Gardener's Reason Why;" Johnston's "Agricultural Chemistry;" Sutherland's "Handy Book of Herbaceous Plants;" Robinson's "Alpine Plants;" Douglas's "Hardy Florists' Flowers;" Sutton's "Culture of Vegetables and Flowers;" Masters' "Botany for Beginners;" Loudon's "Self-Instruction to Young Gardeners," and if possible a copy of his "Encyclopædia of Trees and Shrubs." Those who desire to strive for self-improvement will find Cassell's "Popular Educator" of great value. I can boast of a much larger and more varied library of useful works than the foregoing list, and nearly all purchased with cash saved by exercising self-denial in the luxuries that too many young men indulge in. The study of British entomology and botany are worthy the attention of young gardeners during the spring, summer, and autumn months, as it affords a very pleasant and instructive pastime. During winter the long evenings may be profitably employed in study, and to relieve the monotony of such occasionally fret and solid carving will be found a pleasant amusement. We can look back on many pleasant reminiscences of both life in the shape of dried collections of wild flowers, insects, and fret-carving.

These notes are penned with a view to assist those of your numerous readers who are yet in their probationary stage, and if they should prove useful I shall not have written in vain.—A YOUNG HEAD GARDENER.

BEAUCARNEA RECURVATA

BEAUCARNEA RECURVATA, sometimes known also by the name of *B. tuberculata*, is an exceedingly ornamental plant. The genus *Beaucarnea* is of somewhat recent introduction, and belongs to the order Liliaceæ. At present there are but few species known, but those with which we are acquainted are all natives of the temperate regions of Mexico. *Beaucarneas* are remarkable for the bulb-like swelling at the base, and an arborescent stem. The swollen base in the species we here figure is nearly smooth, but in some others it becomes rough and woody,

resembling somewhat the Elephant's-foot plant (*Testudinaria elephantipes*) of the Cape of Good Hope.

As an ornament to the conservatory, for giving a tropical effect to the outdoor garden during the summer, or for hall decoration either in summer or winter, there are few plants to excel *Beaucarnea recurvata*, its ample spreading head of long, drooping, dark green leaves affording a

mostly in their wants and requirements being very imperfectly understood, and their rarity and consequent high money value has prevented their owners from experimenting much with them.

I have had a great number of these plants under my care both in a large state and as seedlings; I shall therefore conclude these remarks with a brief summary of my mode of management, which has been very

FIG. 33.—BEAUCARNEA RECURVATA.

contrast which we seek in vain in any other plant. It is frequently remarked by both amateurs and gardeners that *Beaucarneas* have a grotesque but not an ornamental appearance. That such should be the case, however, is entirely the fault of the cultivation. Treat them liberally, and an ornamental, graceful, spreading crown of leaves will be developed; starve them, and they become simply ugly. This peculiarity is not confined to the genus *Beaucarnea*, but applies more or less strictly to nearly all the plants we have in cultivation; the fault lies

successful. I find that even in quite a young state, say when only a few months old, the plants begin to assume the bulb-like character at the base; but I am not able to arrive at any satisfactory conclusion as to how long it takes to form such a plant as that represented, but I should imagine it would be about fifteen years from seed, providing the plant received uniformly liberal treatment. The soil should be rich fibrous loam, with a liberal admixture of sharp river or silver sand. Special attention must be paid to the drainage, which must at all times be in

perfect order. The treatment for old plants should be during the summer, if standing in the conservatory, full exposure to the sun, and an abundance of water. I repeat the words, an abundance of water, for the plants may be almost kept with their roots in the water and their heads in the oven. As autumn comes on gradually withhold water, until, upon the setting-in of winter, you may entirely stop the supply, and keep the plants quite dry until the sunny days of spring again set them in motion. I prefer growing young seedlings in more heat, and not drying them quite so much until they get a few years old, when they may be placed upon the same footing as their elder relatives.—E. C.

PEACH TREES AT WILTON.

LEST Mr. Simpson should think me discourteous, I beg to say, in reply to his remarks in reference to what has been written about these trees, that until the trellises were fully covered the extension system of training was practised, and the same method would have been followed had the trellises been four times as large. When the writers referred to by him saw them, they had neither been winter-pruned nor root-pruned, nor do I think there will be much necessity for either of these operations at present, as the annual crops of fruit they have borne have counteracted to a great extent the tendency to form exuberant growth. Should the necessity arise I shall not hesitate to root-prune and apply such materials to the borders, and provide such an atmosphere, as will assist in preventing too vigorous growth.

In respect to branch-pruning, I have endeavoured to avoid the necessity for this operation in winter by frequent and timely pruning during the period of growth, a practice which I think is peculiarly advantageous in the management of all stone fruit trees. True, this method entails increased labour at the busiest season, and in these days of restricted labour it is with great difficulty that they can always be performed at the proper moment; but where they can be there is no difficulty in placing a branch where, and only where, it is required, and so avoid to a great extent the necessity for winter pruning. The labour at my command will not permit of this work being performed always at the proper time, consequently these trees are not by any means so perfect as I could wish, nor so good as I fear the reports of them have led some readers to believe.

The credit of first using the transverse trellis has been wrongly ascribed to me, although I may have been the first to apply it on a large scale and in early forcing houses. My reasons for doing so were not so much for the purpose of carrying out the extension system of training as to secure great variety, lengthened and continuous supply of fruit, and a total increase of training space without in any way obstructing the requisite amount of light and heat on the back wall, on which Fig trees are trained. These cross trellises give exactly 109 square feet of space for each tree, which I am aware is small enough. Twelve trees can be planted by fixing double trellises under each rafter 8 inches apart, and the total training space thus secured is nearly three-quarters more than would be obtained by a longitudinal trellis.

From two similar houses we have, during the last three years, succeeded in obtaining an almost daily supply for five months by commencing with Early Beatrice Peaches in the end of April, and finishing with Walburton's Admirable Peaches and Victoria Nectarines in September. I beg to thank Mr. Simpson for his friendly invitation, which I hope some day to be able to take advantage of; in the meantime it will afford me great pleasure to see him at Wilton. He must, however, not anticipate seeing such perfectly trained trees as I fear he has been led to expect.—T. C.

CRINUMS.

It may be said with some truth that numbers of beautiful bulbous plants are never likely to prove satisfactory under cultivation in this country owing to its being apparently impossible for us to provide the requirements necessary to their health. Certainly a better knowledge of the nature of some of them has enabled us to succeed where success once appeared impossible, and this may be taken as hopeful promise of still more of the rarer bulbs proving satisfactory when their peculiar requirements in respect of heat, light, and moisture are better understood; but that many others ever will prove serviceable garden plants seems with our present knowledge almost beyond hope. The Crinums, however, do not fall in this category. They are, generally speaking, the easiest to manage among tropical and temperate bulbs, so that in the threescore or more species of which anything is known we have a large number of beautiful and easily grown plants, worthy of considerable favour wherever bulbous plants are grown. The species of Crinum known and grown in this country do not comprise all nor yet half of the number above mentioned; but when once the demand for them increases we may expect to see some of our enterprising plant-collectors turn their attention to un-introduced Crinums.

Now-a-days it is customary to inquire into the capabilities of plants for hybridising purposes, and the greater the promise of their proving plastic in this respect the more the importance and value attached to them in a horticultural sense. So far as is known, the whole of the Crinums cross freely with each other.

Dean Herbert, whose labours among the Amaryllis family enabled him to produce a work upon them which for interest and valuable information is one of the finest botanico-horticultural books ever written, devoted much time and attention to hybridising and crossing different plants; in fact, it may be said that to him we are indebted for the magnificent forms of Gladiolus and Hippeastrums we now possess, for he was the first to experiment on the original forms of both these genera with a view of raising improved races. Writing upon Crinums he said, "It is almost certain that the fertility of the hybrid or mixed offspring depends more upon the constitutional than the closer botanical affinities of the parents. The most striking and unanswerable proof of this fact was afforded by the genus Crinum, which is spread round the whole belt of the globe within the tropics, and within a certain distance from them, under a great variety of circumstances affecting the constitution of individuals, which nevertheless readily intermix when brought together by human agency." The importance of this statement will be at once seen by those who understand the art of hybridising. What has been done with the Hippeastrums seems achievable in the case of the Crinums; for both in the variety of form and colour of their flowers, the habit and nature of the plants of this genus, there is abundance of material out of which excellent garden plants could no doubt be produced. It seems reasonable to attribute the little attention paid to Crinums to a lack of knowledge of their beauty, usefulness, and capabilities. If once they be thoroughly understood and properly put to the test, the result must be a great gain to cultivated bulbous plants.

The species of Crinum represented in gardens do not number more than a dozen, if we exclude what are known only in botanical collections. At Kew there are about thirty species and a dozen or so varieties, and as these include both tropical, temperate, and hardy sorts, the flowering seasons of which extend over the whole year, it is seldom that there are not some in flower in that establishment. Of those to be met with more or less in gardens generally, the following perhaps comprise the whole, exclusive of varieties and erratic names which always exist in garden nomenclature.

C. amabile.—The bases of the leaves in this species fold tightly over each other, so as to form a neck or stem about 18 inches long. The leaves are about 3 feet long, pale green, and curving over. A healthy plant bears from thirty to forty leaves together. It is evergreen, and bears in December a long-stalked umbel of white sweet-scented flowers, as many as forty of these flowers being borne in one umbel. On the under side of the segments of the flowers there is a stripe of bright red. Each flower is about 8 inches in length, the segments being half an inch wide and curving downwards. The stamens are red. Being a native of Sumatra this species requires a tropical stove temperature.

C. americanum.—The bulb is short-necked, as large as a Belladonna Lily bulb. The leaves are from 2 to 3 feet long, and number about ten on a healthy bulb. The flowers are very fragrant, pure white, and are borne in sixes on a stalk about 2 feet long, each flower measuring some 8 inches in length, with spreading lance-shaped segments. A beautiful species, and almost if not quite hardy in the south of England. It is well established in a border against a house in the Glasnevin Botanic Gardens, and is also planted outside at Kew. Commencing to flower in the summer, it continues to produce its sweet-scented blossoms until cut down by frost. A native of the southern States of North America.

C. angustifolium.—The Australian representative of the last-mentioned; distinguished, however, by its shorter leaves, flower stalk and flowers, and by the latter being tinged with red on the under side. It is a tropical species, preferring a dry sandy soil and a rather dry atmosphere. The flowers, which are scentless, are produced in summer.

C. augustum.—The bulb of this when fully developed measures a foot in length and about half that in diameter. The leaves are between 2 and 3 feet long and 4 inches broad. The flattened flower scape is produced from the side of the neck of the bulb, and is nearly 3 feet in length, bearing an umbel of between twenty to thirty flowers, which are 4 inches long, bright red on the outside, and white tinged with red inside. It is found in the swamps of Seychelles and Mauritius, so that it requires stove treatment with us. The flowers are produced in early summer, and last about three weeks.

C. campanulatum.—Often known is *C. aquaticum*. It is a native of South Africa. The bulb is egg-shaped and as large as a swan's egg. In foliar and floral characters it resembles *C. americanum*, differing in the purple colour of its flowers and

their shorter length. It is a beautiful species, and thrives well in a cool greenhouse. It flowered at Kew last year.

C. capense.—Sometimes called *Amaryllis longifolia*; a common Cape species, and is one of the best known in this country. Planted in a well-drained and sheltered border it grows and flowers freely all summer. There are two forms of it, a red-flowered and a white-flowered one. The bulb is *Amaryllis*-like, with a short neck, and the leaves from 3 to 4 feet long. The flower scape is 18 inches long, and bears an umbel of from six to twelve flowers, which are from 3 to 4 inches in length, the segments being about an inch wide. Herbert says of this plant "It is a very hardy species, endures the winter, and flowers in profuse succession during five or six months in a bed covered with leaves in the winter. It delights in wet, and will flower in a pond. In a warm situation it may remain always in water." As a companion to the *Belladonna Lily* in borders out of doors the two varieties of this *Crinum* will be found exceedingly useful.—W. W.

(To be continued.)

THE PINE APPLE NURSERY, MAIDA VALE.

MESSRS. E. G. HENDERSON & SONS' nursery in the Edgware Road has for many years been one of the most noted of London trade establishments for plant-growing, and there appears great probability that under the present energetic management its prestige will be still further increased. The almost innumerable glass houses have been long devoted to an extensive collection of miscellaneous plants, but special attention is now being paid to the more popular and useful classes of plants, though all the meritorious rarities are carefully preserved. Large stocks of young plants are being raised in all departments, several new houses have been erected and others are about to be commenced, while in the outdoor department the fine collection of hardy plants has been advantageously re-arranged. Other improvements are under consideration, and the general aspect of the nursery indicates a most pleasing and vigorous activity. A few notes upon the chief features will enable readers to form an idea of the collections.

ORCHIDS.—These have deservedly received a considerable share of attention for some years past, and many thousands of the most useful and choice cool and tropical species and varieties are now grown. *Odontoglossums* have several houses devoted to them, such established favourites as *O. Alexandræ* and *O. cirrhosum* being represented by numbers of the best varieties obtainable; the plants being almost without exception in robust health and showing and bearing abundance of flowers. The charming little dwarf *O. Oerstedii*, which continues for so many weeks in flower, is in capital condition, and is certainly one of the best of the small-flowered type. *Masdevallias* are in strong force, especially *M. Lindenii*, *M. Harryana*, *M. Shuttleworthii*, and *M. Veitchii*, while some of the smaller and less conspicuous forms, such as *M. triangularis*, are interesting; but the most remarkable of all in regard to numbers and profusion of flowers is the white *M. tovarensis*. Of this useful Orchid one house contains some hundreds of plants as healthy as could be desired, not a sign of "spot," and quite a sheet of bloom, some of the spikes bearing three or four flowers each. Either for effect or cutting, this is an indispensable plant in any collection of Orchids. *Cattleyas* and *Lælias* are in vigorous health, showing sheaths abundantly and promising a fine display later in the season, though many of the *C. Trianae* section already brighten the houses with their richly coloured flowers. Three span-roofed houses with open stages over large tanks of water are principally occupied with *Dendrobies*, *Phalænopses*, and *Cypripediums*, the latter being exceedingly good; the growths stout and of that fresh healthy green tint which is so pleasant to the eyes of an Orchid grower. Other houses are devoted to miscellaneous collections of *Aerides*, *Vandas*, *Trichopiliæ*, *Sophranitis*, and all the principal genera.

PALMS.—A dozen or more of the really useful Palms that have been proved to be of substantial decorative value are grown by hundreds, and a most satisfactory stock of young plants is now steadily advanced. The indispensable and graceful *Cocos Weddelliana*, the much-enduring *Seaforthia elegans* and *Areca lutescens*, the sturdy *Phoenix reclinata*, and the beautiful *Kentia Fosteriana* and *Canterburyana*, occupy several houses, and are chiefly about the size most suitable for decoration. Moreover, as they are not grown in the steamingly high temperatures too frequently accorded to Palms, their leaves are of firmer texture and better capable of enduring changing temperature, dry air, and exposed positions of rooms, corridors, &c.

FERNS.—The *Todeas* at Pine Apple Place, it is well known, are always alone worth a visit, and they are just now preparing for the production of their annual handsome crowns of young fronds. *Adiantums*, *Pterises*, *Davallias*, and other favourite genera are represented by thousands of plants in all stages, from the "spore pan" to exhibition specimens. Several novelties are included, but particularly good is a pretty variety of our true Maidenhair Fern, *Adiantum Capillus-Veneris gracilis*, which is distinguished from the type by its larger and more compact fronds and closer neater habit. It is to be sent out this spring, and will no doubt receive the favour of many Fern-lovers. *Selaginellas* are receiving much attention, the number of species and varieties being very large for a trade collection. Many beautiful forms of these plants are much neglected in gardens, and except a few of the *S. Kraussiana* habit comparatively few are generally

grown, yet *S. hematodes* and others of the erect or frondose group are rivals of some of the most elegant of Ferns.

MISCELLANEOUS PLANTS.—The general stock comprises greenhouse *Rhododendrons* of all the standard varieties now being rapidly increased, double *Primulas*, one of the finest collections of varieties and plants, Tree *Carnations*, *Passifloras*, *Camellias*, *Marantas*, *Bromeliads*, and scores of other stove or greenhouse plants, most of which have houses specially devoted to them. *Imantophyllums* are numerous, some of the specimens are of considerable size, and showing flowers in large numbers. *Blandfordias* are well grown, the varieties being remarkable for the rich colour of the flowers. In one house specimens of a pretty little plant are growing in small pans suspended from the roof, and though as yet in an infantile stage they are likely to become extremely ornamental. This is honoured with the somewhat lengthy title of *Saxifraga sarmentosa tricolor superba*, and differs from the tricolor known in gardens by the leaves possessing an unusually broad pure white margin, which contrasts very agreeably with the bright rosy young leaves, and the emerald centre of the older ones.

The occupants of the large conservatory have been re-arranged with praiseworthy taste, and some artistic additions have been made to the rockery, which have greatly increased the beauty of this handsome house. Every department, in fact, affords evidence to the practical skill brought to bear upon the work by the experienced manager, Mr. Hollands, who has already done much to increase the fame of the establishment in the horticultural world.

ELCOMES REGISTERED IMPROVED FUMIGATOR.

MR. ELCOME of Woodland Road, Upper Norwood, sends us one of his new fumigators, which is represented in the annexed figure. Its claims, as enumerated in the prospectus, are "simplicity in construction and economy in operation, as it will burn any sort of

Fig. 34.

tobacco paper, rag, or card, without attendance, in close frames or greenhouses." Several gardeners who have tried the fumigator testify that it has given them great satisfaction. It appears to be a handy, light, yet durable article, and we see no reason that it should fail to accomplish the purpose for which it is designed.

MANCHESTER HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.

At the fortnightly meeting of this Society, recently held in the Old Town Hall, King Street, Mr. Bruce Findlay, the President, in the chair, there was a large attendance.

Mr. W. Nield read a paper on "The Apple," which, he said, is unquestionably the best and most useful of all hardy fruits. Though it possesses many good qualities, the Apple has not received from those who till the soil anything like the amount of attention to which it is justly entitled. According to the agricultural returns for 1883 there were in England 185,782 acres of land planted with fruit trees. If 35,782 acres, a liberal estimate, were deducted for land planted with Pears, Plums, Cherries, and Filberts, there remained 150,000 acres devoted exclusively to the cultivation of Apple trees. About seventy standard Apple trees can be grown on an acre, so that the total number of trees would be 10,500,000. There are probably as many Apple trees grown in hedgerows and farm orchards, not returned as such, and market gardens, as are grown on all the land specially devoted to their cultivation. This would bring up the total number of Apple trees to 21,000,000, or nearly one for every individual in England. If one-half is deducted 10,500,000 trees still remain, and, assuming each tree to bear two bushels per annum, the yearly crop would amount to 21,000,000 bushels, the market value of which at 4s. per bushel amounts to £4,200,000. Supposing the trees to be grown in 150,000 acres, the annual value of the crop would be £28 per acre, which, with good cultivation and a better selection of sorts, might easily be doubled. In fact he did not know of any purpose to which the land could be put which would bring in so large a return for the capital employed, if farmers and market gardeners only knew how to go about it. He pointed out that demand for raw fruit is increasing in a greater ratio than the population. We have now from 3000 to 5000 different names for Apples, though he very much doubted if we have anything like that number of varieties in cultivation. The greatest number of sorts ever collected together was at the recent Apple Show held a short time ago in London,

when 1800 named varieties were exhibited, and 900 of these were afterwards shown in Manchester and Birmingham. Mr. Nield then gave some useful suggestions as to the cultivation of Apples. It is his intention to publish the paper in book form.

The Chairman, Mr. F. J. Broome, Mr. Birkenhead, Mr. Richard Astley, Mr. Thomas Worthington, and Mr. Plant took part in the discussion which followed. Some severe strictures were passed by several of the members on Mr. Kynaston's pamphlet on "Out-door Fruit for the Million."

Mr. Plant remarked that practically what Mr. Kynaston had written in his pamphlet was worthless and absurd, and it had been the cause of much unpleasantness between gardeners and their masters and mistresses.

The Chairman said the views set forth in Mr. Kynaston's book were misleading, and those persons who had the slightest faith in those views possessed a very superficial knowledge of the subject.

Mr. W. Swan, the Honorary Secretary, said he would have liked each member to have brought to the meeting a few Apples grown in his particular district, so that the members might have decided which were the best varieties that could be produced in the vicinity of Manchester. He suggested that the names of the varieties should be sent to him in order that he might submit them to the next meeting.

NOTES ON ORCHIDS.

DENDROBIUM WARDIANUM.—Calling a day or two since upon Mr. Keeling, the able gardener at Mount View, Sheffield, I was shown a remarkably fine display of this beautiful Orchid coupled with a large general collection of other Orchids, such as *Phalenopsis*, *Cœlogynes*, *Odontoglots*, *Cattleyas*, *Oncidiums*, &c., now in bloom. The plants of *D. Wardianum*, numbering over fifty, are mostly in full bloom, and a large proportion of them are very strong pieces, having each six to ten strong breaks with four to six flowering growths, many of which are 4 feet in length, and on one growth I counted thirty-one blooms. Among them are some very fine varieties with blooms 4 inches in diameter. One especially I noticed, being very heavily tipped on the sepals and petals with a bright magenta-crimson, the lip also beautifully coloured. The plants are nearly all grown in baskets suspended from the roof with the flowering growths hanging in a natural manner, in which position they are much more effective and beautiful than when grown in pots and the growths stiffly tied to stakes. Mr. Keeling also finds that with him the growth is much more satisfactory in baskets than in pots.

ONCIDIUM SERRATUM.—In the same house with the *Dendrobes* is a plant of *Oncidium serratum* with a branching spike of flowers over 16 feet in length, and carrying upwards of fifty blooms. The flower spike is suspended to the roof immediately over the pathway, and has a very striking effect.

PHALÆNOPSIS SCHILLERIANA.—Flowering very profusely are several plants of this fine Orchid. One of them, carrying two flower spikes with twenty flowers on each, has produced a young plant with a leaf 8 inches long upon one of the spikes at about 18 inches from its base.

Cœlogynes are very fine, especially a pan of *C. cristata* *Lemoniana* with twelve spikes of six and seven blooms each. Especially noticeable also are some beautiful highly coloured varieties of *Cattleya Trianae*, with a fine collection of *Odontoglots* and *Masdevallias* now in bloom. A large span-roofed house about 60 feet by 20, built by Messenger, is very gay with a fine collection of bulbs (*Hyacinths* and *Tulips*), *Cinerarias*, *Cyclamens*, and *Camellias*, making with the Orchids a combined display of choice flowers such as is rarely seen, and of which the spirited proprietor (D. Ward, Esq.) and his gardener may feel justly proud.—W. K. W.

ODONTOGLOSSUM ROEZLII.—This and its variety *alba* are amongst the most beautiful and useful Orchids we have for cutting. It is very graceful for vases, also for personal adornment. Good-sized plants may be grown in 5 or 6-inch pots. Those who possess half a dozen plants or more can generally find a spike or two amongst them, for they produce flowers more or less all the year round. To keep this *Odontoglossum* in good health it must be grown warmer than the *crispum* type: 60° to 65° as a minimum temperature, 5° extra as a maximum, with a proportionate rise in summer and abundance of light, but not direct sunshine. It must never be allowed to become dry at any time of the year, and when in full growth it will require a large supply, also damp well between the pots twice a day. A good guide with this class of *Odontoglot*, as well as those that belong to the *O. crispum* type, is to supply sufficient water to keep the sphagnum in a healthy growing condition, and the plant will generally be the same. The sphagnum must not be allowed to overrun the bulb, or it will cause the stem to damp. A good guide I find is to supply water when the tips of the sphagnum have a white tinge on them, but not a parched appearance. The water should be applied through the rose of a syringe, as it can be given more regularly than with a watering pot. The best

season for repotting this *Odontoglot* is November. Thrips are a great enemy if allowed to gain headway; it disfigures its beautiful foliage very much. On the first appearance of the pest it should be dipped in a preparation of nicotine soap.

ODONTOGLOSSUM VEXILLARIUM.—This requires the same treatment as *O. Roezlii*, except that the temperature which should be lower: 50° to 55° as a minimum in winter, with 5° extra by fire heat for the day temperature, with proportionate rise in summer. Although these Orchids do not like a close atmosphere they must not be exposed to draughts, which would be fatal to their well-doing.—A GROWER.

LYCASTE SKINNERI.—Is it an uncommon occurrence for *Lycaste Skinneri* to produce twin flowers on one spike? The second this season is just opening with me, and I do not remember to have seen this before. The plant which is flowering just now has the flowers curiously blotched and marbled.—R. P. B.

PHAIUS GRANDIFOLIUS.—This deserves to be largely grown; and flowering as it does just now when most of the *Calanthes* are over, it is the more useful. Those who possess a plant of *Phaius grandiflora* should shake it out and pot singly in 32's; employ good loam, charcoal, brick rubbish, and sand; grow it in the stove along with the ordinary collection of stove plants. It likes the treatment good gardeners give their stove plants. When fresh potted it should be shaded from bright sun till well established, when it will need more light to consolidate the growths. It must be placed in a greenhouse temperature for a few weeks in the autumn and kept a little on the dry side. After this slight rest it can be brought on in heat to follow the *Calanthes*. I treated an old plant in the way described last year and made a dozen plants of it, nine of which at the present moment are carrying over 250 blooms and buds. One was given to a lady which carried away with it three good flower spikes, and two have not flowered at all.—G. MERRITT.

THE YOUNG GARDENER QUESTION.

Now that the fire of criticism on the advice to young gardeners by "A Working Gardener," and on the allusion made respecting them by me in my communication in our Journal of December 26th, 1883, is dying out, it becomes my duty, as one who opened the subject, or at least who said a hearty yes, yes to the one who did, to give a word or two in reply. I may at the outset, perhaps, be allowed to say how surprised I have been all through the discussion of this subject to find that so few have caught the spirit of goodwill towards young gardeners that shines between every line of "A Working Gardener's" exhortation, or to recognise the good-humoured banter that I tried to put into my words. Only "Wiltshire Rector" in his annual homily in the Journal of January 3rd, 1884, seems to have a notion that all that was said by "A Working Gardener" and myself was said with an unselfish and loving desire for the best interests and truest happiness of our younger brethren. His kind and gentle allusions to our writings, and his wise, sympathetic, and encouraging words of advice to young gardeners, are such as well becometh the Christian priest, and worthily and fitly commence our volume for 1884. I say here also a hearty amen to the Editor's charitable and hopeful words touching the young gardeners that appear in his greeting "To our Readers." It does one good to hear that he can, from his wider outlook over the gardening world, testify that his experience of young gardeners is of the brightest.

Taking the letters of criticism in the order in which they have appeared I may say that "A Philistine" (January 3rd) has utterly misapprehended the spirit of my words. I must tell him, and others also who have made the same mistake, that I am as far from being hypochondriacal as light is from darkness; that I am ever one of the cheeriest of men, a condition or state that I am more grateful to God and my parents for than for any other possession I have. Not only in "A Philistine's" letter, but also in one or two others, I have noticed the flavour of a sneer running through them. This is a failing which every public writer should guard against more than almost any other. A sneer is a weak man's argument; and though to a young writer it may appear to add an element of smartness to his composition, he may rely upon it that others will not so consider it. This is a leaf out of the book of my own experience. I am too old to be moved by it, except to regret to see an otherwise good letter spoilt by it.

In the same number of the Journal and under the same heading "A Young Gardener" has a letter which is the strongest proof (if proof were needed) of my charge as to "skimming and slighting" reading. The letter is superficial all through, though on reading between the lines one is conscious that, barring the superficiality, there is a good and worthy fellow at the back of the pen. To show the on-the-surface style of reading of your correspondent, I need

only point out that the quotation from Shakespeare which he makes is only half right. He says, "Beatrice said she could easier advise twenty than be one of the twenty to follow her own instruction." Well, Beatrice said nothing of the sort in "Much Ado about Nothing;" but Portia, in "The Merchant of Venice" (act i. sc. 2), says, amongst other good things, "I can easier teach twenty what were good to be done than be one of the twenty to follow mine own teaching." I admit that the spirit of the quotation is right, but nothing shows a sound reader so much as a perfect quotation. Go deeper, my young brother, there's a good writer in you; and whatever you do always verify your quotations. Why one of the writers on "Stored-up Sap in Vines" should go out of his way to give me a back-handed slap in the face by signing himself "Not H., Notts," I do not know, except to show that he desires to advertise himself as having no connection with me, and let us hope neither of us will be any the worse for our isolation.

In the Journal of January 10th "T. L." charges me with being prejudiced against everything and everybody of the present day, and concludes, after advising young gardeners to cultivate a taste for music, that I cannot possibly be a musician, and must be a very dismal and melancholy man. All his charges and conclusions are wrong; and with respect to not being a musician, I can only say that music is the joy of my life: that I was put up into a choir to sing as soon as I could sing, having to stand on a stool to be seen: and that I have been choir-singing ever since, up to last Sunday, when I took my place on the cantors' side as leading tenor in the surpliced choir of the church where I worship. So much for one of "T. L.'s" conclusions. "T. R. M.'s" letter answers itself. It is a contradiction; it opens with blame and closes with thanks. "Querist," in the Journal of January 17th, begins by saying that there is a striking difference between the communications of "A Working Gardener" and "H., Notts." Quite so, "Querist." No one knows that better than I do, though you discount your judgment by your after suggestion that I should have supplemented "A Working Gardener's" able communication by pointing out the best way in which knowledge of the subjects enumerated could be most advantageously acquired. That is to say, you put me down by telling me that I cannot write so excellent an article as "A Working Gardener" has done, and then you blame me for not writing a better one, and even improving on that of "A Working Gardener." Paragraph the second in "Querist's" letter admits all that "A Working Gardener" and myself charge young gardeners with almost. Read it again, "Querist." My answer to "Querist's" demands are in this wise: If you want a job done do it yourself; where there's a will there's a way; don't talk, work; go at the first thing and do it well, the next will show itself when you're ready for it; look up, go forward, and keep doing; no man ever rose to greatness that talked about greatness; genius is a great capacity for taking trouble. "Every man has two educations—that which is given to him and the other that he gives himself. Of the two kinds the latter is far the most valuable; indeed, all that is most worthy in a man he must work out and conquer for himself. It is this that constitutes our real and best nourishment. What we are really taught seldom nourishes the mind like that which we teach ourselves."

Finally, be assured all ye young gardeners, we who are older and who point out your failings and weaknesses are not your worst friends. You will find as you go on in life that he is our worst friend who is always telling us what fine fellows we are and how clever we are. Personally I, with three young people belonging to me, aged respectively twenty-one, nineteen, seventeen, am only giving in public the same advice I give in private, and though they are not gardeners, I am thankful to say not being drawn to my profession, and I considering that it is very much overstocked, yet counsels of industry, thrift, economy of time as well as money, and warnings against present day allurements, are applicable to all young folks in whatever state of life they may be. I say again, as I never lose an opportunity of saying, that it is largely due to the excellent advice of the old writers in the *Cottage Gardener* and *Journal of Horticulture* that I owe my present satisfactory position. I repeat, my satisfactory gardening position. I do not say high position. Once I was as ambitious as any other young man, but the faithful teachings I received in these pages, and my own observations, soon taught me that it is not the highest positions in the gardening world that are the most satisfactory, or where a man may be most useful and comfortable in life. Wherever I was I always strove to do the best I could, and if everyone will do that honestly, his position in life that he is best fitted for will surely come to him sooner or later; and the best he can do is to go on doing the duty that lies nearest to him, and he will find that the next duty will reveal itself. If it should be that there are two ways lying before him, both of which look like duty, let him choose the roughest. The Editor is now looking for the signature. Here it is again.—H., Notts.

[On page 65 we intimated that two letters then in hand on this

subject would be published, but for others we feared space would not be available. Notwithstanding that intimation still more communications have reached us, and we have deferred the publication of the reply of "H., Notts," in the hope of finding room for them. We have failed in doing so; and as many articles await insertion, and as the two letters promised appeared on pages 84 and 85, we can no longer delay the reply of our Notts correspondent. Further discussion on this subject must be necessarily postponed until the pressure on our columns is relieved. It is due to the able "Young Gardener" who made the Shakespearean slip to state that he discovered his mistake, but his correction reached us just too late for insertion.]

KITCHEN GARDEN.

Tomatoes.—These are gaining favour annually, and many who knew little of them a few years ago are now anxious to grow them well and extensively. Ripe fruits may be had under glass from Easter until Christmas, and in the open air from July until November. The best way to grow them under glass in early spring and late autumn is to treat them like Cucumbers; but they may be grown under glass throughout the summer without any artificial heat. Seed should be sown now to produce plants for all purposes. As a yellow variety of the finest flavour Carters' Prolific is unsurpassed, Vick's Criterion is very early, Crossling's Glamorgan remarkably free, and Trentham Fillbasket and Reading Perfection are also good. As a rule the seed germinates freely, and a large quantity need not be sown to raise a few dozen plants. About two dozen seeds may be sown in a 6-inch pot, and the plants potted as required till they are ready for planting out, or many fine early Tomatoes may be gathered from plants grown in 10-inch and 12-inch pots.

Potatoes.—Seed Potatoes are now forming young growths, and where they are thickly stored in mounds those at the bottom will suffer. The best of all ways is to spread the seed tubers in a single layer in a light airy place, and let the young shoots form if they will. Apple-rooms are becoming empty, and the shelves there are capital places on which to lay out the seed Potatoes. Ours are annually subjected to this treatment, and they have always robust shoots about 1 inch long at planting time. A quantity of the earliest varieties may be planted in a south border or at the bottom of a south wall or hedge. The sets of kidneys should never be cut. Plant in rich soil and cover the sets 4 inches deep, but never plant unless the weather and soil are favourable.

Potatoes in Frames.—These are now growing rapidly. Protect them carefully from frost, and add surface soil where the young tubers are too near the light. Thin the stems where they are crowded. Two strong growths will be more valuable and productive than eight or ten that are weakly. Admit air when the sun is shining.

Radishes.—French Breakfast and Wood's Early Frame varieties should be sown on a sheltered border; a small bed will suffice. Frequent sowings in small quantities are the most satisfactory. Those coming up in frames should be thinned to 2 inches apart. Ventilate freely in all favourable weather. Winter varieties may be cleared off the ground as soon as the spring plants are ready.

Cauliflowers.—Those wintered under handlights and in frames must now be hardened-off as the weather will allow, as they should be quite hardy before being transferred to the open borders. Keep the lights off altogether on fine days, and when the nights are not very cold only put them on partially. Sow seed in gentle heat, and if the plants are grown without being checked it is astonishing how rapidly they will come on.

Kidney Beans.—Sow these in frames, pots, or boxes. Osborn's Forcing is still the favourite. Put pieces of birch to those coming into fruit to keep the plants up. Gather the pods before they become aged, so as not to check the development of the young ones. Keep plants in bloom in a dry atmosphere until the pods are formed. Encourage young plants by giving them more root room. A rich soil and a temperature of 65° or 70° advances them rapidly now.

Brussels Sprouts.—A pinch of seed may be sown in a pot or box to produce a few scores of plants for early use or exhibition. Do not force them on in any way, but merely keep them steadily growing. A frame will forward the plants some weeks before any can be raised in the open soil.

Garlic.—This may be put out now. Treat it as advised in *halls* a fortnight ago.

Carrots.—French Horn and English Horn varieties may be sown in a border. The soil must be moderately rich, open, and free from grubs. Sow in rows 1 foot apart, fill up the drills over the seed with sand, and tread or roll in. Young Carrots in frames now require more air, and many of them will be benefited by being thinned.

Stored Roots.—Carrots and Beetroot stored in sheds are now pushing growths from the crowns, and as these destroy the qualities of the roots they must be kept rubbed off before they have gained any great proportions. Turn over the roots, remove those decaying, and store afresh all that are good, as it will yet be some time before young produce can be had in quantity.

Cabbage.—A sowing of some good early Cabbage if made now will be found most useful in June and July. Make up all blanks in those which have been growing in their bearing quarters during the winter. Autumn-sown plants in seed beds, if becoming too crowded, should be thinned. If not wanted to plant elsewhere it is better to throw some of them away than have them all spoiled.

FRUIT-FORCING.

VINES.—*Early Houses.*—The first thinning of the earliest Grapes being brought to a close, and a good watering given the inside border, employing tepid liquid manure at a temperature of 80° to 85°, the berries will swell rapidly—i.e., the perfectly fertilised berries, until they reach the stoning stage; but before that is reached the bunches should be examined a second time and the heaviest shoulders tied up. It may probably be necessary to remove a few more of the berries, especially those showing evidence of weakness, as it is desirable to have the berries as near as possible of an even size. It is also necessary, when the second thinning is being attended to, to calculate the probable weight each rod will be likely to finish, and if this is considered a full one, or over-fu one, no time should be lost in removing the worst-placed and poorest bunches, so as to leave no doubt of the crop being perfect in finish. The strongest spur shoots having been tied down and stopped two or more joints beyond the bunches, the leaders and laterals should be allowed to grow until every part of the trellis is well filled with foliage, at the same time allowing sufficient room for its development and full exposure to light. Maintain a genial condition of the atmosphere by damping the floors and borders at closing time, admitting a little air at 75°, and maintaining a temperature of 80° to 85° through the day from sun heat with ventilation. Sprinkling the borders occasionally at closing time with liquid manure will be beneficial in keeping red spider in check.

Succession Houses.—The Grape-grower has plenty of work before him, as Vines when in growth must have prompt attention. Encourage succession houses by closing early with sun heat and plenty of moisture well charged with ammonia from the mulching, or if there is no mulching sprinkle the borders with liquid manure, also the paths and walls. Do not keep a close moist atmosphere, as that tends to form long-jointed wood and thin flabby foliage, but admit air freely on all favourable occasions, avoiding a high night temperature, giving a little air on warm mild evenings. Disbud as the most promising shoots advance, and do it gradually, and do not be in a hurry about stopping, allowing the shoots to get well ahead of the bunches before doing so, and then not less than two or three joints beyond the bunches. Where there is space allow the first laterals to extend according to the space at command, taking into consideration their ultimate development, it being necessary that the foliage have full exposure to light.

Late Houses.—The treatment advised for succession houses is now applicable to late kinds of Grapes intended for keeping through the coming winter. A little steady fire heat in the spring is much better than running the risk of having to ripen them in a cold sunless autumn, when hard firing becomes a necessity, and the concomitant exclusion of air to secure the needed temperature only aggravates the evil the cultivator seeks to avoid—viz., badly ripened Grapes—not coloured to the shank, and not keeping to a late period without shrivelling. It is better to start in March than have to push the Vines in autumn, when external conditions are less favourable; besides, late Grapes, as a rule, require a long period of growth, and especially for ripening, as compared with the thin-skinned varieties.

CHERRY HOUSE.—The trees started as advised in previous calendars will be flowering, or nearly so, when it is essentially necessary to utilise every favourable occasion for ventilating the house freely and for setting the fruit. If bees are near it will not be necessary to resort to artificial impregnation; but if not, it must be effected artificially, and should be done if possible when the house is freely ventilated. Begin to ventilate a little at 55°, giving air plentifully at 65°, closing for the day at 55°, maintaining a temperature by artificial means in the daytime of 50° to 55°, and dispense with it altogether at night unless the temperature is likely to fall below 40°, between which and 45° it should be maintained through the night. Although it is not advisable to syringe the trees whilst in blossom, damp the borders and paths in the morning and afternoon of fine days, modifying the moisture in accordance with external conditions. A strict look-out must be kept for aphides, and if those are present the best remedy is to fumigate with tobacco paper, being cautious in its application, as the foliage, being tender, is soon injured.

PLANT HOUSES.

Azaleas.—Plants that have been forced into bloom and are now past their best should be placed into a temperature of 50° to 55° at night, a Peach house or vinery being suitable. They should not be stood back into a cold house as is too often the case. By assisting them to make their growth at this season, forcing next autumn and winter will be easy. Before introducing these plants into heat be careful that there are no thrips upon them, or the foliage will soon be injured. These insects are easily destroyed by syringing or dipping the plants in tobacco water with which a little soft soap has been mixed. If the plants have commenced growth and their roots are active, potting, if necessary, may be done. Potting these plants should always be attended to when they require it, and not left until a good number can be done at one time. The soil around the roots should always be moist before being turned out, and small shifts are preferable to large ones. The soil should consist of good fibry peat and coarse sand, and requires to be pressed into the pots very firmly. The roots should not be disturbed more than is necessary

in the removal of the old drainage from amongst them. Give the roots every chance of recovery from injury received in potting, by withholding water as long as possible without allowing the soil to become dry. The system of applying water to settle the soil cannot be too strongly condemned. Those that do not require potting may have a sprinkling of Standen's manure on the surface. After potting has been done the plants and pots should be liberally syringed and the atmosphere kept moist.

Heaths.—The early-flowering varieties, such as *Erica hycmalis*, *E. Wilmoreana*, and others, that failed to flower last autumn and were cut back, have started freely into growth, and their roots have commenced action. In this condition, if they require it, they are ready for transferring into larger pots. If done at once the plants will have every opportunity of being established before the sun has much power. They will have a long season before them in which to make and ripen their growth, and if properly attended to will not fail to flower abundantly early next autumn. The compost should be the same as that advised for Azaleas, and the same care should be taken in the potting and watering. After potting place them in a frame close to the glass where frost can be excluded in severe weather. Keep the frame close for about a fortnight, and damp the plants lightly with the syringe on bright days, and then gradually admit air, which should afterwards be given liberally during favourable weather. A close confined atmosphere must be avoided, or the plants are soon attacked by mildew.

Epacris.—The plants that have flowered should be cut close back, and if any are bare at the base or tall they will not be injured if cut hard back into the old wood provided they are healthy and vigorous. It is surprising what strong growths healthy plants will make when subjected to hard pruning; in fact, it is the only system by which they can be furnished again from the base in a season. A vinery just starting is a good place for them if frame room is limited, but the latter is preferable if the plants can be given a temperature ranging at night from 45° to 50°, according to the weather. They should be gently syringed twice daily during bright weather, and the frame closed about 2 P.M., which will soon start them into growth.

French and Fancy Pelargoniums.—The earliest batch of these should now be established in their largest pots, and if they have been kept close to the glass the plants will be strong and sturdy. The shoots must not be stopped again, but tied out to light stakes. Place them in a night temperature of 50° close to the glass, and give air liberally when favourable; a little at night will be beneficial when mild. No attempt should be made to grow these plants in a close atmosphere, or they will soon draw up tall and weakly; on the contrary, grow them strongly and keep them dwarf. The shoots of the later batches should be pinched as they require it and potted as the plants are ready. Employ a compost of good fibry loam and a seventh of manure and sand. Pot firmly, which will assist materially in obtaining a firm solid growth instead of a soft one, with a long distance between the joints. Keep these plants in a temperature of 45°, and supplying water carefully for some time yet. Fumigate at once if aphides appear on them. A batch of cuttings for late flowering will root well if inserted singly in small pots and placed on a shelf in any warm house.

SEASONABLE NOTES ON BEES.

THERE is a tendency among those who for the first time are possessors of bar-frame hives to miss the happy medium and to err by going to one or the other extreme. Those of the one class are too fearful, cannot screw their courage to the "sticking point," while those of the other give the rein to vaulting ambition which o'erleaps itself and falls on the other side. Perhaps those in the second category fail more often, and do much more injury to the cause of bee-keeping in general than those who are at first too timid to make rapid strides in creating a proper intimacy between themselves and their bees. Instead of "screwing their courage," &c., they are rather too fearful of the sticking points which their favourites possess, and this wholesome dread often acts as a salutary deterrent from unnecessary and injurious meddling. Where the at first timid bee-keeper gradually gets on good terms with his bees, and constantly by cool quiet approaches learns how and when to handle them, to read the lesson they teach him, and to put his ever-increasing knowledge into practice, that man will in time become a bee-master. But he who makes a toy of the new hive, never ceases to be meddling with it and its inmates, does not care for their stings in season and out of season, exposes them to chills and their combs to derangement, this man is likely soon to throw up bee-keeping in disgust and to bring ill-repute on the bar-frame hive and the modern system of management. With the skep it was not possible to interfere so much with the economy of the bee hive, and even when interfered with so little was to be seen of its internal government and arrangements that the temptation was not so great to repeat the inspection often. But since Huber spread out

its combs as the leaves of a book, until the development of the present bar-frame hives open to inspection from end to end, and at any moment the temptation to invade the privacy of the insect home has grown in the same ratio as the abilities to do so.

An expert of a County Bee-keepers' Association told us the other day that he believed the bar-frame hive in the hands of many cottagers had proved a failure, owing to the injudicious manner in which the bees and brood were so constantly exposed to the chances of a chill. He went a step further, and said he believed he had traced the spread of foul brood in his neighbourhood from hives which had been thus carelessly used. Whether chilled brood will eventually bring about the fell disease, "foul brood" depends on various circumstances; but whether or not this be the case ultimately, a whole neighbourhood is endangered by a reckless owner of hives. We would, therefore, attempt to impress on all young bee-keepers the great care they should make it incumbent on themselves to take as to the manner and time of overhauling their hives, and this advice especially applies to this season of the year. We know that there are some who advise stimulative feeding to be begun about the middle of February. Our own experience has shown that it is better to commence this artificial excitement a little too late than too early. We have in most seasons being guided by the flowers as to the time to commence feeding bees for the purpose of stimulating the queen to lay eggs and the workers to raise brood. When the Crocus flowers have been well in bloom we have considered it time to commence gentle feeding. But what an extraordinary season this is! If we had looked to the Crocuses for the word of command this year we might have commenced feeding any time between New Year's day and the present date. Crocuses, Primroses, and Violets, besides many other spring flowers, have been plentiful in all the southern counties during the whole of the winter (?) months. Then what is to guide us in such a season as this? Certainly not the flowers. We would look to the condition of our hives, see that they are not in any want of food, and then wait patiently until March begins.

We find that breeding has more or less been going on for some time in our hives, probably the greater part of the winter. Compared with other years the consumption of food has been great. Since October 9th up to date of writing our registered stock has decreased in weight by 15 lbs. This would mean the consumption of a greater weight of food than the 15 lbs., for there is a quantity of brood in the hive, and brood weighs very heavy, whereas when weighed in October there was no brood. This points to the necessity of careful observation to see that hives do not run short of food. Where it is needed of course a supply must be given, but we would give it all at once. Where combs of honey have been carefully kept during the winter they will be the best of all food, at the same time seeing that there is a good supply of water near the apiary and easily to be got at. When breeding is going on there is a heavy draw on the water supply. For this reason, when once stimulative feeding is commenced, the best food for the purpose is thin syrup. By giving the supply of water thus much labour, and consequently loss of life, is saved.

But to return to our former advice. We would avoid for the present all stimulative feeding. Breeding is already going on too rapidly for the good of the stocks; a sudden spell of very cold weather will endanger the brood if it is too rapidly spread over the hive. The bees must contract the surface now covered by them in the event of severe frost, and the cluster may not be sufficiently large to cover the brood. The result will then be chilled brood, which will not only greatly retard the building-up of the stock, but may endanger its very existence. Again, stimulative feeding, having been once commenced, must not on any account for a single day be discontinued; it is, therefore, obviously wise that it should not be commenced until such time as natural conditions will permit of its steady continuance. So to all bee-keepers we would say, Keep the bees as quiet as possible for at least another fortnight. We will then, for the benefit of those who, perhaps for the first time, use a bar-frame hive, or may be for the first time handle bees, endeavour to explain what we are doing with our own bees in order to work them up to proper strength for giving either swarms or supers in due season.—P. H. P.

TRADE CATALOGUES RECEIVED.

- J. Backhouse & Son, York.—*List of Alpine and Herbaceous Plants.*
 Jules de Cock, Faubourg St. Lievin, Ghent.—*Catalogue of Plants.*
 Biddles & Co., Loughborough.—*Illustrated Catalogue of Seeds for 1884.*
 W. A. & E. Gill, Victoria Nursery, Lynton, North Devon.—*List of Ferns and Bedding Plants.*
 W. & J. Birkenhead, Fern Nursery, Sale, Manchester.—*Catalogues of Ferns and Selaginellas.*
 William Paul & Son, Crossflat Nurseries, Paisley.—*List of Florist Flowers.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (S. B.).—It is quite impossible that any man can "acquire knowledge like 'Single-handed'" by the study of any one book, and as a rule it is better to procure a number of comparatively inexpensive works on different subjects than one very large volume that is necessarily costly. Thompson's "Gardeners' Assistant" is a comprehensive and good practical work. You will find a list of useful books in another column, recommended by a gardener who has proved their value, and who has turned their teaching to excellent account. When plants and flowers are sent in the same parcel mistakes sometimes occur, as the specimens have to be examined by different authorities. Inquiry shall be made on the subject.

Poinsettias (J. S.).—The suggested notes are sure to be of service to many readers, and we will readily publish what you may obligingly send.

Cyclamens (C. P., Bracknell).—You have an extremely good strain of Cyclamens, equal to many of the best exhibition varieties, and both foliage and flowers indicate excellent culture. The dark red variety is much like one certificated last year as Mr. H. Little.

Seedling Croton (G. R.).—The leaves are very richly coloured, and somewhat resemble Comte de Germiny and C. Williamsi, but your best course would be to exhibit a plant at one of the Royal Horticultural Society's meetings, and obtain an expression of opinion from the Floral Committee.

Dendrobium nobile (B.).—Thanks for the beautiful examples of this Orchid, which will be more fully referred to next week.

South American Plants (Eighteen-years Subscriber).—We cannot determine the true names of the plants from the titles sent, but if you send us some of the seeds we will endeavour to procure the names for you. Probably 1 is a species of Aristolochia, and 2 a Canna.

Seedling Rhododendron (C. H., Bucks).—The trusses of bloom sent resemble R. altaclerense, a hybrid obtained from crossing R. arboreum with R. catawbiense. It is one of the earliest to flower, but is often injured by frosts and keen winds in the spring.

Limes not Succeeding (C. R. R.).—Limes usually flower freely in the south of England, and it is probable that your district is too cold for them. The flowers contain all the essential organs, but rarely produce seed in this country, though it ripens readily on the continent. We cannot recommend a dealer, and the other information you require could be obtained from the advertisement columns of a trade paper.

Grasses for a Wet Cold Lawn (A Young Gardener).—The ground having been efficiently drained, it will be suitable for a greater variety of Grasses than it is now. In its present state it will only be advisable to employ Poa trivialis 12 lbs., Poa pratensis 12 lbs., and Agrostis stolonifera 4 lbs., with about 6 lbs. of Trifolium repens, along with 24 lbs. of Lolium perenne tenue. With the ground well drained, and a good dressing of lime—about six tons per acre—applied and worked in before sowing, we see no reason why you should not employ a mixture of the finest Grasses—viz., Cynosurus cristatus 8 lbs., Festuca duriuscula 6 lbs., Festuca tenuifolia 2 lbs., Poa trivialis 4 lbs., Poa pratensis 4 lbs., Poa nemoralis sempervirens 4 lbs., and Trifolium repens 8 lbs., adding Lolium perenne tenue 24 lbs., so as to bring up the mixture to 60 lbs., a proper quantity for an acre. Spare no pains in forming a good tilth, which is essential to a speedy and good germination of the seeds.

Pruning Fruit Trees (A. M. B.).—Cordon fruit trees planted in the autumn should be pruned at once by simply shortening the side or lateral growths to within half an inch of the stem from which they issue, and the leader to the extent of about two-thirds of its original length. If trees have been taken up carefully, and have abundance of roots, severe pruning is less needed; still, all trees that have been removed suffer root-mutilation more or less, and the shortening of the growths becomes necessary to effect as near as possible the desired balance of strength between root and branch. Standard trees should have any small twiggy branches removed; the others, from four to six, shortened about half their length. A stronger growth and foundation for a good head will thus be insured. Bush trees require pruning on the same principle as cordons, a selection of shoots being made and regularly disposed for forming the main branches, the side growths cut in as directed, and the extremities shortened for forming a well-shaped and symmetrical tree. The main branches of a bush fruit tree should be about a foot apart.

Water Melons (G. W. T.).—You will be able to grow Water Melons in your district in the same way as ordinary Melons, either in frames or houses. In some parts of the United States, where the summer temperature

high, they are grown out of doors like ridge Cucumbers are in England. The Water Melon is known botanically as *Cucumis citrullus*, and is a native of tropical Africa and the East Indies. It serves both for food, drink, and physic to the Egyptians. It is eaten in abundance during the season, which is from the beginning of May until the end of July. It is the only medicine the common people use in ardent fevers; when it is ripe or almost putrid, they collect the juice and mix it with rose-water and a little sugar. The fruit should be eaten cautiously by Europeans, especially when taken in the heat of the day; but it is much used within the tropics and in Italy. The seeds are employed to a considerable extent as a domestic remedy in stranguary, and they are esteemed by some as diuretic.

Camellias Unhealthy (H. S.).—The root-action of the plants is defective, as it will be, no matter what kind of soil is used, if the leaves are permitted to be scorched by the sun. Some persons assert that Camellias can be grown without shade. Healthy specimens with vigorous root-action and abundance of water can be so grown, because moisture in sufficient quantity can be supplied to the leaves to maintain their freshness, notwithstanding the evaporation from their surfaces; but such plants as yours, and unhealthy plants generally, cannot be exposed to the sun or a dry atmosphere without injury, as under such conditions the moisture is extracted from the leaves faster than it is supplied by the roots, and scorching and blotching follow. Grow your plants in a moist, moderately warm, and shaded house, syringing them frequently, and if the soil is suitable, as you appear to think it is, and sound judgment is exercised in watering, they will improve considerably if they are not too exhausted.

Various (Idem).—We are not able to state the name of the particular variety of Grape to which you allude; but bunches 6 lbs. in weight are every year produced of Black Hamburgh, Black Alicante, Gros Colman, Gros Guillaume, and Muscat of Alexandria by many cultivators. You will find notes on glazed and painted pots in another column. The name of the town in question is Weston-super-Mare. Probably the "Lily of the Valley Tree" you refer to is *Clethra arborea*, which was figured in this Journal, page 131, August 14th, 1879. The flowers are white, fragrant, and somewhat resemble Lilies of the Valley in form.

Briars as Tree Protectors (E. Mason).—The method to which you allude of securing Briars to the stems of standard fruit trees was communicated to us a few years ago by Mr. Hiam in the following words:—"During the last few years I have adopted a very simple and effective method of protecting young fruit trees standing in a field from the injury caused by cattle rubbing against them. It may not be new to some readers, but I have never seen trees similarly protected, but on the other hand I have noticed many an orchard spoiled in appearance for the want of a little attention, and it cannot be out of place to call attention to my method. The system I have adopted with considerable success is, placing a few of the most formidable Briars of one or two years' robust growth around the trees, two or three round a young tree 1 inch in diameter, and so on up to about half a dozen round trees 6 inches in diameter. Since I have adopted this plan three years ago I have not found one tree touched. If the cattle once try it they will immediately become convinced the Briars are not placed there for their accommodation. After placing the thorns round the trees they are securely bound with a couple of wires top and bottom, and will last for three years at least. A dressing composed of about equal parts of cow dung and clay mixed in a bucket, and which is diluted with water which has previously stood on gas tar, is rubbed on the tree with a whitewash brush. Perhaps a portion of quicklime would be a useful

Fig. 35.

addition, but that has been omitted because it was not at hand. The odour of this composition is obnoxious to the cattle or rabbits, and is no doubt useful in destroying insects or preventing their attack."

Stephanotis (G. P., Hants).—You had better start your plant in heat without further delay if wanted in bloom by the date you mention. If you have during the past month or two kept the plant drier and cooler than an ordinary stove temperature it will soon be excited into growth if introduced into the stove. If started now an ordinary stove temperature will suffice, and it is always wise to start even a little too early than to push the plant forward in too brisk heat. Should your plant during the month of June be developing too rapidly you can easily retard it by placing it in a lower temperature; this, when time will allow, is an advantage, for the flowers will possess more substance, and be much larger and more highly scented than if forced out in sharp brisk moist heat. They will also last longer. We could give you a certain date from the records of past years for sowing the Peas you mention, but this would not be wise, for if the season proved hot and dry they might be ready too early for you, or if wet and cold they might be late. It would be advisable to make two or three small sowings during the present month instead of one large one. Those sown about the middle should be right for you if the season proves favourable.

Manure for Roses (J. B.).—You do not say one word about the condition of your Roses, whether they grow strongly or the reverse, which is a most important matter in considering your question. Some soils are so strong that Roses make slow growth, at least for a time, being long in getting established. In such a case abundance of gritty matter, such as ashes, with road sweepings, also decayed vegetable refuse and farmyard manure not too much decayed, would undoubtedly be the best material to apply, and no artificial manure, however good it might be, could give equally good results. Again, no artificial manure has the same effect on different soils, because of the differing constituents of the soils, and by no other means can a person ascertain the best manure for his own case so well as by trying the effects of a few that can be conveniently obtained. The fertiliser you name we have seen answer admirably for Roses and other outdoor crops, but it appears that you possess evidence that it is of "little or no use." Can your friends explain to your satisfaction why a particular manure is good for vegetation under glass but of little use in the open? Guano is an excellent stimulant for Roses, and so is a mixture of superphosphate of lime and sulphate of ammonia, while in all probability a liberal dressing of soot would be of great benefit in your strong soil. A mixture of urine and soapsuds poured copiously among the roots is often highly advantageous, equalling anything else that is applied. If your Roses grow freely you may obtain fine blooms without farmyard manure, but you can scarcely expect to rely on producing them of the "highest exhibition quality." Mulching the soil either with manure, short grass, or any other material in summer, to prevent its cracking, is always beneficial. By this practice, and the aid of liquid manure judiciously applied, you ought to be able to produce very good Roses.

Neglected Azaleas (I. M.).—So far as we can understand the condition of the plants it is questionable if their lost vigour can be restored. In all probability the majority of the roots "hardened into a ball" are dead, and it is quite hopeless your attempting to wash the soil from them. Even if you could do so you would gain nothing, as you could not get fresh soil in its place. There is only one method by which such "wretched" plants can be improved, and that is what timid persons would adjudge ruthless. It is to take a sharp axe or chopper and boldly cut off an inch or so off the bottom of the hardened ball, and a similar slice from all round the sides. The dead roots would then be cut away, and the live portions, if any, be brought into immediate contact with the fresh compost, in which the root-pruned plants may be potted. Before potting, take particular care that the mass of soil and roots is moist. If dry, as it possibly is, immerse in a pail of water for several hours, then allow the superfluous moisture to drain away by a few hours' exposure to the air. The ball when potted must be decidedly moist all through, but not in a wet mortar-like state. As compost use peat mainly, with a little decayed leaf soil, about a fourth, and a liberal admixture of sand. This must be healthily moist when used, but not so wet that a drop of water can be squeezed out of it. Let the pots be cleaned and well drained, protecting the crocks with a layer of fibre, then place in a little soil and press it down very firmly—sufficient to raise the plant so that the top of the ball is brought within about an inch of the rim of the pot. Now place in more soil, a little at a time, and beat it down quite hard with a blunt stick. The compost placed in must be quite as hard as that of the original ball. Too light potting of root-bound Azaleas is a common error, and often a fatal one, as the roots in such a case never "take to" the new soil, while the water that is given never passes through the old. The result is this—the new soil is made sour by saturation, while the roots packed in the hard central mass starve by want of the water that runs from them into the lighter medium. After being potted as directed the plants should be placed in a warm and moist house. If the pots can be partially plunged in a bed of leaves all the better, as less water will be needed to keep the soil moist, for moist it must be, but not excessively wet, while the plants must be syringed frequently—twice or thrice a day in bright weather. By judicious applications of water, this being an all-important matter, Azaleas in the condition that yours appear to be—starved, stunted, and root-bound—may often be greatly improved; but whether yours are "too far gone" for restoration we are not able to say—because, first, we do not know their exact condition; and secondly, so much depends on the means at your disposal and the cultural skill you are able to command in attending to the plants. Such stubborn plants must not be cut back. Only Azaleas that are in vigorous growth can be closely cut every year, as many plants are that are grown for yielding flowers for cutting, the removal of these being as much pruning, and often more, as is good for the specimens. We trust this reply will be of use to you; if not, it may be of service to others, as there are hundreds of Azaleas in a very unsatisfactory state that might be improved by the intelligent adoption of some such method as we have suggested.

Names of Plants (J. R., Bury St. Edmunds).—The plant of which you have "tried in vain to obtain the name" is *Sparmannia africana*, which is noted in another column under the head "Useful Plants."

Hives and Quilts (H. G.).—We have never used, or known to be used, bacon boxes for hive-construction, and should be fearful that the salt would be detrimental to the welfare of the bees, especially in a damp climate, if the wood were thoroughly impregnated with it. If we employed the wood of these boxes at all, it would be only as outside walls, using inner walls of well-seasoned deal, and stuffing the space with chaff, and using separators front and back between the combs and the front and back walls of the hive. Salt in itself would not hurt the bees, but the dampness caused by it would be bad in winter. Racks of sections can be worked with profit and facility on the round-topped cheese boxes. Take care to wrap them up warm, and give a quarter-inch space under the sections between them and the top of the cheese box. Having such a small entrance to them as the feed-hole, we should not employ excluder zinc. The quilts on bar-frame hive should be removed when the section rack is put on, placing it directly on the top bars, and taking great care to wrap up warmly over and around it, so as to prevent all draught and escape of heat from the body of the hive.

COVENT GARDEN MARKET.—FEBRUARY 27TH.

THE better trade has been well maintained, Grapes more particularly realising higher prices. Strawberries lower, in little demand.

GRASS SEEDS FOR LAYING DOWN LAND TO PERMANENT PASTURE.

(Continued from page 160.)

THE seeds for good loams possessing a fair quantity of humus or vegetable matter, and at the same time being dry and friable, must be next considered. Generally speaking, these soils will, if properly manured, be rich enough to produce abundant crops of Grass in permanent pasture. The following varieties, four of which Mr. Faunce de Laune describes as the four coarse Grasses, are valuable beyond all others for permanent pasture:—

	lbs. per acre.
Cock's-foot (<i>Dactylis glomerata</i>)	12
Timothy (<i>Phleum pratense</i>)	4
Dog's-tail (<i>Cynosurus cristatus</i>)	4
Tall Fescue (<i>Festuca elatior</i>)	4
Meadow Foxtail (<i>Alopecurus pratensis</i>)	4
Yarrow (<i>Achillea millefolium</i>)	4
White Dutch (<i>Trifolium repens perenne</i>)	4
Cow Grass (<i>Trifolium pratense perenne</i>)	4

Total quantity per acre..... 40 lbs.

Referring to the seeds here named and included for good loamy land, it must also be remembered that nothing beyond ordinary tillage will be required if the land is clean, except green crops, &c., ploughed in, because we are now alluding to soils which are naturally fertile enough to produce fair crops of Grass, especially if these are made equal to the requirements of full crops by previous manuring and cultivation; and we mean by this preparation that in case of the land for some years having been regularly manured and tilled under alternate husbandry it will require very little extra cultivation. In the event of the soil having become foul with couch a fallow will be required for the full term of a long, or winter and summer fallow, and it should be sown with Wheat in the month of October, after the application of a good dressing of yard manure. If the land is rough and cloddy so much the better, because when the seeds are sown at the end of March or first week in April the clods will then afford abundance of fine mould for burying the seeds. Where no manure is laid on, 3 or 4 cwt of bone superphosphate may be applied at seed time with the Wheat, and 2 cwt. of nitrate of soda in February or March at the time of sowing the Grass seeds.

The preparation should be as follows:—Commence working by giving several times with heavy iron lifting drags, then roll with the Cambridge iron four-horse ring roller, and then sow the heavy and light Grass seeds separately, one lengthways, the other crossways, as the grooves formed by the rings of the roller will accept the seeds, and one or two times with the chain harrow

following will effectually bury them with the fine pulverised earth obtained by the breaking down of the weather-beaten clods. In this way all these sorts of seeds which are very small will not be buried too deeply, as the grooves made by the ring roller form the best seed bed for regulating their depth.

Our reason for sowing the Grass seeds in the Wheat in preference to Lent corn is because we found that they take much better in the young Wheat than when sown in the Barley or Oats, but especially when the Wheat is sown after a crop of Potatoes, for then the weather-beaten surface affords a firm and favourable seed bed. Again, we prefer sowing Grass seeds in the young Wheat rather than upon a naked fallow, as the Wheat during its growth protects the young Grass plants until the harvest during which time they obtain a strong root-hold on the soil without being overpowered by numerous kinds of weeds as when sown on a fall w surface, in which case they would require to be mown down, weeds and all. Another point is, that after the Wheat has been harvested the young seeds, which should not be fed off by sheep under any circumstances in the autumn, will become strong and well established before the adverse weather of our winter commences. If an over-abundant growth requires it let it be fed lightly by young cattle. As soon as the Wheat is cleared off the seeds should be rolled with the heavy ring roller. This will press the land firmly round the roots of the young plants, and insure their successful root-holding before the approaching winter sets in.

The best kinds of seed to be sown upon a very different class of soils compared with those which we have just provided for—viz., light soils resting on chalk, gravel, sand, or limestone—may now be considered. Although the manuring and treatment of the land may be rather different in some instances, yet the seeds we shall name are well adapted and quite adequate to any difference of aspect or climate in the kingdom. The list we propose for sowing is as follows as to sorts and quantities:—

	lbs. per acre.
Cock's-foot (<i>Dactylis glomerata</i>)	12
Dog's-tail (<i>Cynosurus cristatus</i>)	5
Hard Fescue (<i>Festuca duriuscula</i>)	4
Sheep's Fescue (<i>Festuca ovina</i>)	4
Smooth Meadow Grass (<i>Poa pratensis</i>)	4
Yarrow (<i>Achillea millefolium</i>)	4
Suckling Clover (<i>Trifolium minus</i>)	4
White Dutch Clover (<i>Trifolium repens perenne</i>)	4

Total quantity per acre 41 lbs.

As it is well known that each of these soils above referred to suffer more or less from dry weather, there is a great reason why we should grow Grasses and Clovers of deep-rooting varieties; and those we have chosen are specially valuable, not only for maintaining a plant on the soils named, but are also very nutritious, and will the second year after the plants are established bear the sharp biting of sheep, although their incisors are very prejudicial to the future growth of some sorts of Grasses and Clovers. It is notorious that these soils all suffer from severe drought in certain seasons. It is also to be remembered that they possess little or no humus or vegetable matters, and, like the strong class of soils referred to previously, may have been robbed of what little they contained by exhausting systems of cropping. We must therefore meet this matter somewhat in the same manner, but for a rather different purpose, for in the strong soils we require a strong growth of haulmy plants where the stems are large and capable of acting in a mechanical manner by opening and loosening the soil, where this is just the reverse on light soils. We should, therefore, grow green forage plants for ploughing-in on the fallows, a succession of succulent plants for the purpose of affording in their decay a large amount of vegetable matters without much woody fibre.

It will be noticed that we have purposely omitted Fiorin (*Agrostis stolonifera*) from our list of seeds upon the soils named, for the reason that, although it is perhaps the best known of all Grasses, it resembles Water Grass or Twitch of some strong soils, especially London clays; and when it is made into hay, which after being given to sheep upon arable land, its waste is sure to leave its seeds and foul the land, and in the same way when the hay wasted by cattle in the yards or boxes, it is sure to find its way into the arable land when the manure is laid out. Although it affords an early and late bite when other Grasses are scarce, and is therefore one of the valuable constituents of pastures, still it is only in those cases where the pastures, as in some of the midland and western districts of the kingdom, which are held and occupied separately and apart from tillage lands; therefore instead of the Fiorin we have introduced the Yarrow (*Achillea*) which is an herb rather than a Grass, but it

is especially liked by sheep as well as by cattle. On dry soils, such as those we are speaking of, it frequently forms one of the principal products for grazing, but it is rare to see it in blossom where sheep are constantly feeding. Although cattle are not so fond of it as sheep, yet before the autumn begins it will be found to be closely eaten and no seed heads remaining. There is another point in favour of this herb in pastures—it roots so deeply into the subsoil, even on the driest land, that it never flinches or seriously diminishes in production in the hottest summers; and from this cause it is found, however close it may be eaten by the sheep, to be constantly sprouting and maintaining a succession of food scarcely realised by any Grass production except Sainfoin or Lucerne. It is even better than these, because the sheep cannot eat the crowns or budding stems to their destruction like Sainfoin, for the Yarrow forms a mass of roots spreading under the surface soil, and is quite independent of any surface injury from which the Clovers, &c., suffer.

Another Grass which is named in this list is the creeping-rooted or smooth-stalked Meadow Grass (*Poa pratensis*). It is a valuable permanent Grass, for its general habit of growth, and by its standing drought well, is specially adapted for the lightest soils. Suckling Clover (*Trifolium minus*) is introduced because we have noticed how well it produces, and how permanent it is on dry chalk, gravel, and all light soils, and we think it a very desirable mixture with white Dutch Clover (*Trifolium repens*) on account of their close-growing habits affording in summer time quite a continual mass of bloom of yellow and white flowers so much relished by sheep.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—It has been a good time for rolling the young Clovers, and now the Wheat should be rolled with a heavy ring roller, both lengthways and crossways, especially upon land where the Wheat was sown after green crops ploughed in; for it will sometimes become root-fallen, as it is called, if the land is not pressed firmly. Some farmers use the Crosskill roller, but this is not so well, because it leaves the land on the surface open instead of pressing it down firm. We very seldom find lea ground Wheat—that is, when sown after Clover, requires rolling if ploughed deep enough, unless the second growth of Clover was ploughed in. We have various experiments in ploughing-in green crops this year which may interest young beginners, because it is a practice not yet so well known as it probably will be. For instance, one-half of a field was Clover lea-dunged, and Wheat sown after one ploughing, the other half of the field was a fallow for common Turnips, grown by an application of $2\frac{1}{2}$ cwt. of bone superphosphate. The Turnips proved large and well grown, and were in consequence a full crop of about 16 tons per acre when ploughed under, but would have reached 20 tons or more probably if left longer. They were, however, intended to be followed by rough chaff Essex dwarf Wheat; 12 tons or less would have been enough if they were followed by Lent corn; in fact, 8 or 9 tons when they have abundant foliage would have been enough for a crop of Oats, and 5 or 6 tons sufficient for Barley if the foliage had been gross. This land is just about being rolled with the ring roller, and will be seeded to Clover and Cock's-foot, and Timothy Grass seeds at the end of March. The next experiment is a piece of land after a crop of *Trifolium* cut for soiling cattle, and then twice ploughed, made clean, then sown with Turnips, with the same amount of manure as for the other field; but being later sown there was an abundance of foliage, but the Turnips never having been hoed were not large, but we consider them quite large enough, and they were as usual chopped with the cross-barred chopper and ploughed in, and the Wheat sown late, it being a dry, friable, and kind piece of gravelly land, but no doubt will produce a full crop of Wheat. Several other pieces or parts of fields have been done in different ways, which we intend to explain at another time.

Threshing corn ricks, both of Wheat and White Oats, has engaged the attention of men and some horses lately. The advantage of doing this work before a busier time arrives is great, for the delivery of the grain to the station or the town will engage some horses, which can be ill spared at the seed time for Lent corn, Potatoes, Mangolds, and also the preparing land for other root crops. The drilling of early Peas and Beans will now be going on. In a few days early Peas will be sown of a sort fit for market if picked and sold green; if not, they will be early to seed and harvest, in which case the land will be scarified and cleaned, and sown with Turnips or Mustard according to the day of the month, the crop in either case to be ploughed in for Wheat. Beans will be put in almost simultaneously, being drilled at about 22 inches will be easily horse-hoed and hand-hoed; and Turnips sown at the last hoeing to be ploughed in also after the Beans are harvested, which will be early, because we drill the early Mazagan variety. Sometimes we drill a portion of late Partridge Peas or Winter Vetches with the Beans. These serve to keep down the weeds and cover all the space between the rows. The chief advantage is, however, to avoid the risk of blight in the Peas by early sowing, and in the Beans when mixed with Peas or Vetches, for both never suffer from blight the same season, the Beans suffering from the black aphides and the Peas from the green aphides. The Vetches when they have blight suffer from the red rust, as it is called, but that is more seldom than other kinds of blight, and only occurs in dry hot summers.

Hand Labour.—Some men will be employed in planting Larch Firs,

for on many estates the timber has been cut, especially since the depression among the tenants upon the estates has prevailed. It will, however, answer a good purpose on various poor soils, not available either as arable or pasture, to plant this land, more particularly upon hillsides unsuited for cultivation. Other men will still be employed in cutting and converting underwood in the coppices. Others may be employed in taking off and shaping the sides of farm roads, and this labour is well spent for two reasons: because the roads will require less horse labour in carting gravel for repairs, and also because the turves of earth removed to complete the water tables or sides of the roads will be useful further on for making compost added to any spare manure for the dressing of pasture lands, and at the same time much earth may be utilised, after being mellowed in heap, for bottoming the boxes and cattle pens for the absorption of the urine, and adding greatly to the manurial resources of the farm.

Live Stock.—The lambing of the long-woolled flocks is now proceeding, and requires constant attention, especially as these ewes generally bring a large proportion of twins compared with the South-downs or Wilts and Hants downs. The weather has been, and still continues, very favourable both for the health of the ewes and the strength of the young lambs as they fall. The peculiar growth of the grass in pasture districts is an unusual feature in the present season, and has been highly favourable for all animals which exist in the open fields. The young lambs should, as soon as they will eat, have Carrots cut small, mixed with crushed Wheat or meal of Wheat; for why should the farmers after making use of their own growth of hay go to the expense of purchasing either kind of cake for lamb food or sheep either, whilst Wheat, in connection with hay chaff and cut roots, mixed with Wheat meal, is a cheap and useful substitute. We see a great and double benefit in feeding with cheap Wheat, as it tends to cheapen the selling price of cake, which the farmers do not produce, and tends to reduce the supplies and enhance the price of Wheat, which is the chief of their grain products. Cattle, especially store animals, have plenty of grass where provision of that kind is valued and reserved for them, but should retire to their yards and shelter sheds at night time, where they may receive any food calculated to maintain their health and condition, for crushed Wheat mixed with chaff would make good trough food for them, especially if some Swedish Turnips or Mangold be mixed with it.

"THE EQUIPMENT OF THE FARM."—A volume of the Farm Handbook series, bearing the above title, by William Burness, J. C. Morton, and Gilbert Murray (Bradbury, Agnew & Co., Bouverie Street), has just been issued and will form a useful addition to agricultural literature. The subject is discussed in eight chapters devoted to implements of the farm, farm equipment, farm capital, farm roads, field fences, the water supply, the farm homestead, and landlords' capital, each of which is succinctly and practically considered. In the appendix a number of useful memoranda are given, including specifications of farm buildings and a list of Land Improvement Acts.

TRADE LITERATURE.—"Farmers do not read" is an expression not by any means uncommon. But is it true? We suspect they do read, and they are abundantly supplied by the enterprise of seedsmen, who provide them with congenial literary fare. Before us are three works of interest to agriculturists. Mentioning them in the order of arrival—namely, Sutton's "Farmers' Year Book," Carter's "Farm Seeds," and Webb's catalogue of farm seeds. These are catalogues and much more. The first-named contains an elaborate illustrated article on "Some Pests of Farm Plants," with practical notes on "Cabbage as a Field Crop." The second, a concise and practical paper on "Ensilage," with "Notes on Permanent Pastures," the last-named giving prominence to the "Clover Dodder," illustrated, and the "A B C of Ensilage." All the works are profusely illustrated with the specialities of the several firms producing them.

REMARKS.

17th.—Cool, fair, with occasional sun.
 18th.—Fine and bright, but cold.
 19th.—Wet early, and foggy nearly all day, but no heavy rain after 9 A.M.
 20th.—Milder, and sunny in morning; showers in afternoon.
 21st.—Windy in early morning, with rain; fine afternoon; overcast in evening.
 22nd.—Hail and rain at 2.50 A.M.; fine morning, with solar halo; dull afternoon.
 23rd.—Showery at intervals.
 Temperature slightly lower than in the previous week, but still considerably above the average.—G. J. SYMONS.

ORCHIDS.

THESE continue to make a steady yet vigorous progress in public favour, and commercially they now occupy a more important position in the horticultural world than they have ever reached in previous years. Sufficient evidence of this fact is afforded by the frequency of the sales both of imported and established plants, by the number of buyers which attend these gatherings, by the good prices still obtainable for rarities and fine varieties, and, even more satisfactorily, by the increasing interest shown by amateurs and the public generally respecting these wonderful and beautiful members of the vegetable kingdom. It is true that there are disadvantages attending this advance in favour, and these have led some to designate it as "a craze" which must sooner or later die out, like the Tulipmania and similar speculative bubbles. But the evils in this case appear to be self-corrective, and will probably lead to the thorough establishment of Orchids amongst really indispensable plants. Orchid-producing regions in the Old and New Worlds are being ransacked for species of all kinds, tons upon tons are dispatched to this country, keeping the auctioneers constantly busy. If continued this must soon have an injurious effect, as the prices will decline rapidly, and growers, finding their plants steadily decreasing in value, will be prompted to dispose of them as quickly as possible. No doubt, however, the importers will soon perceive this, and discontinue, before it is too late, efforts calculated to injure their own trade.

To obtain the best evidence of the advance Orchids are making we must not go into noblemen's gardens or the leading gardening establishments, but seek in the suburbs of great cities like London, Manchester, and Birmingham, the residences of our merchant princes. In the present day these gentlemen have done much for horticulture generally, and Orchids they seem to have now taken under their especial care. The result is that scores of wonderful collections have been formed and are continually increasing. Some of the most excellent examples of cultural skill can also be seen in these establishments, for in the majority an experienced man is employed to devote his whole time and attention to the Orchid collection, and, as with all special studies, the peculiar requirements of every species are thus ascertained and provided for. As a rule, too, magnificent displays of flowers are produced at certain seasons of the year, as, with few exceptions, the most freely flowering species are grown in large numbers—*Odontoglossum Alexandræ*, for instance, often by the thousand, and other popular species of the same genus in like proportion. *Masdevallias* furnish a wealth of colour, as also do the *Dendrobes* and handsome *Cattleyas*, while the rarer but often equally beautiful species add many attractions to the displays. As proofs of the popularity of these plants with wealthy commoners the following notes on three representative gardens are submitted, but many other similar establishments are to be found within a short radius

of London, notably at Selborne, Streatham; and Downside, Leatherhead, while they also abound in the neighbourhood of provincial towns.

FERNSIDE.

At Bickley, in Kent, there are two admirable examples of suburban collections of Orchids—one at Fernside, the residence of H. M. Pollett, Esq., and the other at Oldfield, the residence of F. A. Philbrick, Esq., Q.C. Both these are model establishments as regards the number and healthy condition of the Orchids grown there, as a few descriptive notes will indicate. Mr. Pollett's houses are not large but excellently constructed, with a rather low roof and large glass, so that the plants have a free exposure to light. Ample means of ventilation is provided, of which full advantage is taken in fine weather—an important aid to the production of sturdy well-matured growth. Beneath the stages are open tanks kept filled with water, which not only affords a continual supply of moisture, but is also convenient for dipping the baskets or blocks in. The stages are covered with small pebbles that have a very clean appearance and retain a sweet moisture around the base of the pots. It is well known how important it is to protect Orchids from drip; and however well a house is glazed there is always much danger in this respect, as the condensed moisture runs from the glass to the sashbars, and thence falls on to the leaves or the flowers of the plant, doing irremediable injury. A very simple but efficient method of avoiding this is adopted at Fernside, and one which might be advantageously imitated in many other establishments. Strips of zinc about 1 inch wide have their edges turned up slightly, perhaps one-eighth of an inch, thus forming a kind of shallow trough; these are then secured to the sashbars by nails, and all the water which accumulates upon them runs down to the base of the roof and then into the tank below the stage without the slightest injury to any of the plants. It is in points such as these that so many valuable hints may be gained from specialists.

Mr. Pollett's collection of plants includes a fine stock of *Cattleyas*, among them being the now widely known, but not always appreciated, *C. Percivaliana*. There, however, it is represented by a variety with a superbly coloured lip, intensely rich crimson, and well developed. It is surprising what a number of varieties of this Orchid have already made their appearance, some being worthless, while others are exceptionally meritorious, as in the case of the variety named *citrina* recently shown at Kensington. Mr. Percival's white variety also is pretty, but it appears to be wanting in substance. A fine display of *C. Trianae* has been a feature at Fernside for some weeks past, *C. Backhousiana*, *C. speciosissima* (one variety with flowers 9 inches across), *C. Skinneri*, *C. exoniensis*, *C. Mendeli*, *C. Mossiæ*, and innumerable others, some in flower and all in most satisfactory health, with large stout leathery leaves and robust pseudo-bulbs, render this part of the collection a never-failing source of gratification to their enthusiastic possessor and his numerous visitors.

One plant just now is remarkably handsome—namely, *Zygopetalum crinitum roseum giganteum*, rather a long title, but if merit is any excuse for a long name this Orchid well deserves it, for it is one of the most distinct of the genus. It was shown at Kensington last year and honoured with a certificate, and it is again in superb condition, bearing five spikes of about two dozen large flowers. In colour this is very distinct, the lip being almost of the *Z. Mackayi* size and shape, with bright rosy purple streaks. The foliage is strong and rich green, giving the plant a most striking appearance. *Dendrobiums* are largely grown, *Cypripediums* are represented by grand specimens, *Vandas* are in moderate numbers, but amongst them a good piece of the valuable *V. Sanderiana*. Numerous spikes of the creamy white *Angræcum citratum* contribute to the beauty of the floral effect. It should be added that *Odontoglossum Phalænopsis* and *O. vexillarium* are extremely well grown in the house with the *Cattleyas*. They are in pans or shallow pots

suspended from the roof on the shady side, and when the sun is bright and the house is not shaded a piece of tiffany is hung on the sunny side of the plants, effectually protecting them when it may not be advisable to shade the whole of the house. Mr. Wilson, the gardener, who is a most careful and observant Orchid grower, considers that the chief points to insure success with *O. vexillarium* is avoiding overpotting, supplying abundance of water, and affording shade. This is his practice, and the results are stout pseudo-bulbs, strong foliage of a fine purplish hue, and abundant large flowers.

A cool house is devoted to *Odontoglossums*, *Masdevallias*, and some *Oncidiums*, and all look equally as well as the occupants of the warmer houses. The collection of *Odontoglossums* is large, including all the best species and a number of distinct varieties, particularly of *O. Alexandræ*, first favourite amongst cool Orchids. Mr. Pollett has also been very successful in obtaining several novelties, the most recent being that shown and certificated at the last meeting of the Royal Horticultural Society, South Kensington, and named in honour of its owner *O. Pollettianum*. This has well-formed flowers, broad sepals, and petals distinctly spotted with chocolate, somewhat suggestive of the beautiful *O. Pescatorei Veitchii*, but more nearly approaching *O. Alexandræ* in form. A single flower is faithfully depicted in the woodcut (fig. 36). *O. elegans* is another Fernside protégé, and very beautiful it is just now, one plant having three fine spikes. *O. Wilckeanum* with two spikes of thirteen flowers over 3 inches in diameter, and richly spotted with brown on a pale yellow ground, is charming. *O. blandum* and *O. cirrhosum* are similarly attractive, *O. constrictum* being quite a shower of blooms, one plant having nine panicles, some more than 2 feet long and gracefully arching over the plant.

OLDFIELD.

Phalænopses are admirably grown by Mr. Heims, the excellent gardener in charge of Mr. Philbrick's large collection, and a prettier house than that devoted to these plants could be seen in very few gardens at this time of year. The plants are mostly grown in baskets suspended from the roof of a small span-roofed house, the stage on each side beneath them being covered with the pretty plant *Cyrtodeira fulgida*, its neat metallic-lustrous leaves mingling with the silver-veined *Fittonia*, the variegated *Panicum*, small Ferns, and *Pilea muscosa* all growing with tropical luxuriance, trailing over the edge of the stage and down the walls at the side. The baskets are hung at different heights, and abundant graceful panicles of *P. amabilis*, *P. Stuartiana*, and *P. Schilleriana*, with *Angræcum citratum* produce an effect which for free and charming beauty we have never seen surpassed in any Orchid collection. A number of species are included, some very strong plants of *P. grandiflora* being evidently thoroughly at home, *P. violacea*, *P. rosea*, and many others imparting interest to the house. They all appear to enjoy the pure atmosphere of Bickley, and the plants flower so freely that the chief difficulty is to prevent over-exhaustion, for *Phalænopsids* when in conditions suitable to their requirements are prone to flower in excess, sometimes to the death. Many valuable plants have been lost in gardens by this means, and it needs a watchful eye and a spirit of self-sacrifice to remove flower spikes when there is the slightest danger of the plant suffering. The Oldfield collection, some readers will remember, was a few years since in a much less open situation in London, where fogs of the typical November hue and density often caused the *Phalænopsis* buds to fall by scores, leaving naked spikes as dreary mementos of the grower's disappointed hopes; yet there the plants grew as vigorously as could be wished, and there was little fear of their becoming exhausted. At Mr. Bockett's, Stamford Hill Garden, *Phalænopsids* have long been grown with similar success, and in several London nurseries the results are the same—*i.e.*, the plants retain their health so long as they periodically lose some or all their flower buds.

The ordinary stove Orchids are in strong force, a large

span-roofed house 35 feet long and 21 feet wide being devoted to some handsome specimens, *Cattleyas*, *Aerides*, *Vandas*, *Cypripediums*, all in first-rate health. A *Sobralia macrantha*, 4 feet high and as much in diameter, is a magnificent specimen, two twin plants of *Angræcum eburneum* near the entrance being notable. In an adjoining house 45 feet long and 12 feet wide *Cattleya Trianae* is flowering profusely, scores of fine blooms being open, varying greatly in colour. Several plants of the fragrant and graceful *Dendrochilum glumaceum* perfume the whole house, and suggest that this Orchid ought to be much more common than it is. What could be better for a stove? and if grown in sufficient quantity to permit the spikes being freely cut it would be invaluable. A portion of Mr. B. S. Williams' celebrated plant of *Zygopetalum Clayi*, of which a figure was given in this Journal (page 319 vol. iv.), has two good spikes, its rich purplish-blue streaked flowers being very handsome. *Eriopsis rutidobulbon* is a curiosity worth notice, because it is showing flowers, and these are rather rare. It is well known to Orchid growers by its shiny black wrinkled pseudo-bulbs which look as if they had been recently dressed with tar, Mr. Heims attributes its flowering to a long and thorough rest he has this year given it. *Lælia flava* and *L. harpophylla*, both useful garden Orchids, but especially the last-named, are grown in quantity, and they well deserve the attention they receive. *L. harpophylla* is indeed unrivalled in colour at this time of year, its neat rich orange flowers being borne most freely, and last for a considerable time. Healthy plants in 48-size pots with three dozen flowers could not be excelled for brightness and beauty by the most profusely flowered *Pelargoniums*.

The *Odontoglossum* house is a three-quarter span, 48 feet long and 12 feet wide, and well stocked with the choicer species and varieties. Prominent amongst them is the "Golden *Alexandræ*," which was certificated at the last Kensington meeting. The ground colour is a pale clear yellow with rich brown spots on the sepals. Several so-called golden varieties have been brought out at different times, but they have mostly had a common defect—namely, the gold did not keep its colour, and the flowers have relapsed into *Alexandræ*s of a very ordinary character. The Oldfield variety, however, appears to be a welcome exception to the rule, for after some time of careful proving it has been found to be true to its name, an "aureum" of the best character. *O. Rossi* is a favourite, these thriving little plants in baskets hung over the walk having from sixteen to twenty flowers each, differing much in the size and colouring, some having the petals suffused with a distinct purplish tint. *Masdevallias* and *Sophrontis* are well represented, the former especially, many species being included, besides the standard *M. Lindenii*, *M. Veitchiana*, *M. ignea*, and *M. Harryana* types, such as the delicately pretty *M. Shuttleworthii*, the small-flowered *M. triangularis*, the rare *M. psittacina* with twelve flowers, the yellow *M. Wageneri*, the *M. Chimæra* group, and several others.

It is worthy of note that the stages and shelves in the houses at Oldfield are covered with a mixture of small shells and ballast, in which are planted tufts of *Selaginella* and small Ferns, which give them a green fresh appearance, and help also to retain the moisture.

SUDBURY HOUSE.

As a third example of suburban Orchid gardens it will be appropriate to briefly refer to Mr. J. D. Peacock's wonderful collection at Hammersmith. This, without exception, is one of the most remarkable in the metropolis, for few would expect to find in that district and adjoining the high road a dozen large houses packed with the choicest Orchids purchasable in this country, and representing a money value of thousands of pounds. The unique collection of Cactaceous plants and succulents has rendered Mr. Peacock's name familiar to horticulturists, and now he has gained an equal degree of fame with his Orchids. The bulk of the collection is contained in a series of houses

arranged somewhat in the form of a quadrangle, two lean-to ranges each 158 feet long in three divisions forming the flanks, while between these are three span-roofed houses each 63 feet long, several others being also fully occupied with treasures. One feature there, is the large numbers that are grown of particular species; for instance, there are something like 8 or 9000 plants of *Odontoglossum Alexandræ* and *O. gloriosum*, which enable the gardener, Mr. Vickery, to do what can be done in few establishments—i.e., cut Orchid flowers by the bushel. Again, in how few gardens can 200 healthy plants of the lovely *Cattleya citrina* be seen! yet at Sudbury House there is quite this number, about half in pots and the others on blocks or small rafts. In regard to these it may be mentioned as a fact worthy of notice that the plants in the baskets are much the stronger, the pseudobulbs being stouter and larger, the foliage also more vigorous and healthy. Those on the rafts are, however, suspended against the back wall, which they serve to furnish in some degree, and are therefore useful. Besides, the plants are perfectly healthy and flower well, but are not quite so satisfactory as those in the baskets. *Odontoglossum Rossi* in an

Fig. 86.—*Odontoglossum Pollettianum*.

adjoining division is represented by hundreds of plants, and the same method is observed with these as with the *Cattleyas* just named. The results also are similar, the plants in the baskets being much the finer, and bearing very handsome flowers. This is a point worth attention, and were the experiment tried with many other Orchids usually grown on blocks it is highly probable that the success would be as marked.

As an example of the manner in which Orchid names are now unnecessarily multiplied, the beautiful *Odontoglossum Sanderianum*, which is now flowering abundantly at Sudbury House, is especially noteworthy. Practically, this is simply a large *O. constrictum*, the sepals and petals being exactly similar in colour and markings, the lip differing very slightly in shape, and having one central instead of two lateral spots. The most striking difference is that *O. Sanderianum* possesses a very pleasing fragrance, but this is not sufficient to give it specific value; and it is regrettable that while so many eminent botanists are endeavouring to avoid the confusion and dissatisfaction that must arise from giving specific value to varietal characters, others are going to the opposite extreme. Still *O. Sanderianum* is undoubtedly a beautiful Orchid, being easily grown, very free and graceful, amply sufficient to recommend it to growers. It would be unnecessary to describe in detail the inmates of the many other houses; suffice it that all the principal genera are largely grown, *Phalænopsis* in particular, and all alike are clean, healthy, and vigorous.

These three establishments will serve to indicate that the attention paid to Orchids in suburban gardens is very far from decreasing, and notwithstanding the dispersion of some of the leading collections of past years there is substantial evidence that the total number of Orchids in cultivation has greatly increased.—LEWIS CASTLE.

NOTES ON POTATOES.

It is a long time since Potatoes have been so plentiful and good as during this winter, and I believe I may safely say that the Potato crop of 1883 was one of the best ever lifted. For this we have principally to thank those who were the raisers or introducers of really disease-resisting varieties, such more especially as *Magnum Bonum*, *Reading Hero*, and *Scotch Champion*. Ours is by no means good land for growing Potatoes, being very heavy and cold, and is also too low-lying to suit them. In spite of these disadvantages we lifted highly satisfactory crops of the three above-mentioned sorts, all of which, owing probably to the very hot weather experienced during August, are of the best table quality.

Scotch Champion is the most certain cropper, and having been found fully satisfactory it will again be planted to the extent of about one-third of the space annually devoted to Potatoes. Ugly it undoubtedly is, the largest tubers in addition being generally hollow in the centre, but they are good from the time of lifting till the end of February. To boil them is quite a mistake; they should be steamed, and then they are floury and good. *Magnum Bonums*, however, do not steam well, and should be boiled. Several new varieties, including some of those alluded to by Mr. Fenn on page 100, and of which that veteran raiser is justly proud, proved disease-resisting and otherwise pleasing, but I shall not discard the *Champions* in favour of any of them, nor do I advise others to do so till further trials have been given them.

Magnum Bonum evidently partly originated with some American variety, both from its foliage and also from the fact of its requiring very hot weather to perfect the crop. Here, for instance, it is not invariably disease-resisting and of the best quality, and the cottagers were fast becoming disgusted with it. Last season's results will cause a reaction in its favour. *Reading Hero* forms the longest haulm of all; but it does not branch much, and is very woody. It crops well, and the tubers can be both boiled and steamed satisfactorily. Those who particularly object to the *Champions*, owing to their ugliness, should give the *Hero* a trial. All should be given plenty of room, the *Champions* growing in rows not less than 40 inches apart, the other two 3 feet apart, and the sets in each case about 1 foot apart. At these distances it is useless to attempt to crop between them.

Turning from the latest to the earliest sorts, I can speak most favourably of the true *Old Ashleaf*, which I first received from Mr. Taylor, and which he grew extensively at Longleat. It makes but little haulm, crops heavily, and is the earliest of all. The tubers are fit for use when three parts grown, but are not good if kept. To succeed these we have *Veitch's Improved Ashleaf* (which appears to me to be similar to *Mona's Pride*, *Early Bird*, and *Carter's First Crop*), and this we grow extensively under the impression that it is the most profitable early sort. It keeps good to the end of the year. *Carter's First Crop* when first grown by me cropped more heavily, but this would appear to be owing to the change of seed, as it cannot now be separated from *Veitch's*. *Myatt's* and *Rivers' Ashleafs* are both old favourites, but either from being later or other causes are more liable to disease than *Veitch's*, and are discarded, preferring rather to grow more of the latter. The best early round is *Early Border*, this making little haulm and yielding a surprisingly large number of good-sized handsome tubers. This variety, in common with the *Old* and *Veitch's Ashleafs*, are excellent for frame culture, and look well on the exhibition table.

We are now very strong in second earlies, many of the newer varieties being included in this section. *Fillbasket* forms sturdy haulm, and yields heavy crops of fairly handsome and good-cooking tubers, but the variety is not so disease-resisting as could be wished, and I give the preference to *Lady Truscott*. The latter is, in my opinion, a model variety for gardeners where double cropping has to be practised. It forms stout and not very long haulm, the leaves being very broad, and produces an exceptionally heavy crop of tubers only slightly diseased, which prove excellent in quality. *Early Regent* (Fenn's) is in every respect a good companion for the last-mentioned. *Reading Russet* is rather more vigorous with me, but yields heavily, and the rough red-skinned tubers are generally of very good shape and quality. *Triumph*, another red round, is the only American variety continuously good with me, and this short-topped heavy-cropping sort is particularly suitable for small gardens. *Beauty of Hebron*, a reddish American kidney, is much grown in

some districts, and is a very heavy cropper, but with us is much liable to disease, and is discarded. Vicar of Laleham was one of the sorts most in demand last season, and as a purple round is much liked on the exhibition table, and no doubt will again be much grown for that purpose. On heavy soil it is much liable to disease, and is besides coarse and poor in quality. Schoolmaster did not do so well as usual last season, and if we had more really good rounds for exhibition purposes would be wholly discarded. On strong land it is apt to become scarred and mis-shapen. If pains are taken not to damage the first strong sprout of the Lapstone, and also in well working the ground for it, this variety rarely fails to perfect heavy crops of handsome good-cooking tubers.

Among exhibition sorts Lapstone is still one of the best, and those who hold a good stock of it need not bother with such presumably distinct sorts as Yorkshire Hero, Devonshire Kidney, Lady Paget, Perfection Kidney, and Magnet. All these I admit will, under fairly good cultivation, yield good crops of the most handsome tubers imaginable, but in every respect bear a close resemblance to Lapstone. I ought, perhaps, to except Magnet, but this differs only in that the tubers are not so beautifully white as the Lapstone. Prizetaker and American Purple are almost certain to produce many handsome tubers, and they are of good quality, but much liable to disease. Trophy, a red kidney, is liable to be wholly destroyed by disease, and is worthless for table purposes. Snowflake (synonym, Pride of America) was always a favourite with me, but here it becomes diseased badly, and it forms a handsome dish, though poor in quality.

Adirondach, a rather coarse red round, crops heavily, and fairly handsome tubers can be selected from it; but Triumph, which it rather resembles, is superior to it. Beauty of Kent, when I first grew it, was good, now it is simply worthless. International Kidney I also find worthless in this soil. Woodstock Kidney and Sutton's Favourite are both fine for exhibition purposes, and Harlequin is a pretty neat-growing round. Ashtop Fluke is a fairly good sort. Other exhibition varieties I have grown at different times, and which are fit for that purpose only are Blanchard, Radstock Beauty, McKinlay's Pride, Manhattan, Model, Red Emperor, Porter's Excelsior, Grampian, and Garibaldi.

Potatoes being so plentiful less fresh seed most probably will be bought, but change of seed is always desirable, especially if this be effected before the first strong sprouts of the kidneys are formed. Many will perhaps be in a position to purchase some of the newer sorts for trial, and this proceeding I strongly recommend, as by so doing they may obtain something that on their particular soil may prove very profitable and good.—W. IGGULDEN.

DIGGING.

MR. INGLIS on page 162 has contributed a very useful "chapter for beginners," for it is an undoubted fact, strange as it may appear, that many young gardeners do not know how to dig. A gardener to gain the respect of the men who may be employed under him must not only be able to tell them what to do, but to show them how to do whatever work may be in hand. There are numbers of young men engaged in gardens who have no opportunity for learning how to use the spade and other implements. Their endeavour is to get into "the houses" as soon as possible, and then their desire would appear to remain there as long as they can. This is a mistake. Every person intending to be a gardener should be able to do every kind of outdoor work, and to do it as well as it can be done by anyone else—indeed better. That should be the aim of all.

There are numbers of persons hoping to be gardeners who are not only quite unable to handle the spade in a workmanlike manner, but if they were sent to turn over a piece of ground they would not know where to begin, and this your correspondent has omitted to tell them. After being dug, the surface of the ground should be level, not smooth, which is quite another matter, but devoid of mounds and hollows. These may be plentiful enough before the work is commenced, but they should never be seen afterwards.

The easiest and simplest of all methods of leaving the ground so level that, if a straight-edge were laid across it, it would rest on every clod, is to commence in the lowest place, and work from the hollows up the hills. The lower parts should always be in advance of the higher, and thus wrong will be found in a great measure to right itself. No matter where the lowest point may be, whether at a side, end, corner, or in the middle, begin there and finish at the highest point. In a piece of ground already level the digging may be straight across, as directed on the page quoted, but otherwise the configuration of the surface must be considered, and the work conducted on the principle of always keeping the lower parts well in advance, and the higher may then be left to take care of itself.—AN OLD HAND.

I should feel greatly obliged if he could suggest a cure. He at once wrote asking me to forward more branches. I did so, and in due time he wrote and told me the bushes were suffering from some kind of Phytoptus, advising me to destroy my plants. I had them at once taken up and burnt. In the autumn I obtained from a friend at Louth some fine Black Currant plants perfectly free from the pest. These did well for eight years, then the pest was so bad I destroyed them. I then planted some bushes free from pest against a north wall. I send by this post some branches. The garden adjoining the vicarage premises has an abundance of Black Currant bushes sadly diseased.—A. FITCH, *Bedale*.

[The specimens received are infested with Phytoptus Ribis, which we regret to learn is so prevalent in the north.]

THE BEST ADIANTUMS.

It is quite unnecessary to give any minute cultural details for these favourite plants, as they are by no means fastidious in their requirements. Good soil is essential, thorough drainage and plenty of moisture when growing, and when the pots are well filled with roots weak liquid manure may be given with advantage. Good yellow fibrous loam two parts, peat and leaf soil making up the other two parts, with a good addition of sharp sand, will form an excellent compost for them. Happily Adiantums are not much troubled with insects, but slugs are very fond of the young fronds, and a small glossy-shelled snail, named *Helix alliarius* on account of its smelling like Garlic, is very troublesome, and a diligent search must be made in the crown for this depredator.

STOVE ADIANTUMS.

A. amabile, Moore.—Named also by Mr. Baker A. Moorei. It is a very lovely species, with shining black stipes, and drooping ovate or deltoid fronds from 6 to 12 inches long, much divided, with the final segments roundish and entire, of a bright almost sea-green colour, with a delicate-looking texture. On account of its drooping character it is admirably adapted for basket culture, or for niches in the wall of the house, or for drooping over a ledge of the rockery; but I think as a basket Fern it has the most charming appearance, the colour and habit enable us to distinguish it at a glance. The fronds are too fragile to be of much service in a cut state, and if they were it would be a pity to cut them for such purposes when the indispensable *A. cuneatum* is grown.

A. ancitense, Carruthers.—A comparatively recent introduction from Aneiteum, whence it takes its specific designation. Introduced by Mr. William Bull. It is a noble species, producing large tri or quadri-pinnate fronds, deltoid or triangular in form, ultimately growing from 12 to 24 inches long, and nearly as much across the base, with dark brown shining stipes; the final divisions are from half an inch to 1 inch long, rhomboidal with the outer margins slightly lobed, smooth; the upper side deep green, the under surface somewhat glaucous. This is a very striking species, with its large arching fronds heavily laden with huge bold divisions, and when grown as a specimen on the stage it will form an excellent permanent feature in the fernery. It will also rank as a good exhibition plant.

A. Bausei, Hort.—This is a beautiful garden hybrid raised by Mr. Bause, and sent out by Mr. John Wills, and has become a general favourite. It produces tripinnate fronds upon nearly erect polished stipes, more or less deltoid in form, prettily drooping; the final segments, which vary greatly in outline, are also drooping, of a light green colour. On the rockery this has a charming appearance, also grown into a specimen plant in a large pot, when it may be used for exhibition purposes with telling effect. This is a very striking instance of hybridism in Ferns; it is said to be a cross between *A. trapeziforme* and *A. decorum*, and it certainly favours the assertion.

A. cardiochlena, Kunze.—Frequently met with under the name of *A. polyphyllum*. Native of Columbia and Peru, and known in some gardens for several years, but only recently very plentiful. The fronds are from 1 to 3 feet high, tripinnately divided, of a bright green colour, with a very graceful habit. It is one of the best for exhibiting, also for the decoration of the fernery. Planted out upon the rockery it presents a noble appearance, growing most luxuriantly, quickly forming a large mass of delicate greenery.

A. caudatum, Linn.—Very different from the last, producing drooping simply pinnate fronds from 6 to 15 inches long, the extremities elongated like a cord, and rooting at the extremities, and bud-bearing; and extremely pretty the plant looks when young plantlets are suspended from the fronds in a basket. The pinnae are less than an inch long, lobed, and villose, of a greyish green colour, and a soft texture. I like this as a basket Fern; no kind is more effective thus employed, especially in a humid atmosphere but of course Nature has intended it to be in such a position that the apices of the fronds may find a home for the buds which are there developed. A very pretty colouring may be had if it is planted out on the rockery. It is found in many parts of the eastern hemisphere, Ceylon, India, Cape Colony, &c. *A. ciliatum* and *A. Edgeworthii* are

THE CURRANT-BUD MITE.—I have read with much interest your article on the Black Currant pest. I think it was in 1869 I sent to the Rev. M. J. Berkeley a small branch from one of my Black Currant bushes, asking him to tell me the disease from which they were suffering, adding

synonyms of varieties at most of this plant, and may be treated similarly.

A. concinnum, H. B. K.—A very lovely species with gracefully drooping tripinnate fronds on shortish black glossy stipes, ovate-deltoid in form, the final divisions cuneate with the edges; the fronds vary in length from 9 to 24 inches, of a rich green colour when mature, delicate pink in a young state. It is one of the most elegant of all the Maidenhairs for baskets, the exquisitely drooping fronds fringing the basket, and ultimately covering it; it is also equally desirable for planting out on the rockery. There is a much-appreciated variety known under the name of *latum* which is more robust, and, as its name implies, very broad in all its parts, the fronds also being more erect—a very decorative and valuable Fern for all purposes. The normal form is a native of Tropical America, widely distributed from the Antilles to Brazil.

A. farleyense, Moore.—This magnificent variety is well known to all Fern-growers. Originally introduced from Barbadoes, and regarded as an abnormal form of *A. tenerum*, which it more closely approaches than any other species. The fronds are large and arching, growing from 1 to 3 feet long, three or four times divided, with the large final segments cuneate or semicircular, deeply lobed and fringed, of a light green colour, with a soft texture. Invaluable as it is for all decorative purposes it is especially useful for the exhibition table, always counting as a weighty plant if in good condition. It enjoys plenty of heat and moisture at the roots during the summer. I have never seen it fertile, although I have heard of its fertility, but I have on many occasions observed the margins of the segments rolled backwards, forming a kind of indusium, but such were destitute of sporangia.

A. Lathomii, Hort.—A noble Fern hybrid—well, of garden origin, said to have been selected from a batch of sporelings of *A. Ghiesbreghtii*. It produces fronds from 1 to 2½ feet long, very broad, ovate deltoid in form, with a drooping habit, tripinnately divided; the ultimate divisions sub-cuneate or half fan-shaped with evenly crenate margins, of a pleasing light green colour, and very thickly set in the pinnules. In habit and contour it resembles the last, and after all it may be but an aberrant form of *A. tenerum*, for imagine how much some Ferns vary, and this will not be difficult to appreciate. By all means grow *A. Lathomii*, whatever its parentage, and you will not fail to regard it as one of the best *Adiantums*.

L. macrophyllum, Swartz.—One of the most distinct and beautiful of the genus, with creeping rhizomes, from which stout black polished stipes are produced, carrying large fronds from 12 to 20 inches long, and from 4 to 9 inches broad, simply pinnate, with a few large pinnæ on each side of the shining rachis, which is from 3 or 4 inches long and 2 or more inches broad, with the margins lobed, of a bright velvety green colour, with a firm texture, when young of a delicate pink colour. It is admirably adapted for pot culture, forming a most effective specimen when in its grandest development, known at a glance from all the rest. Native of the West Indian Islands and Mexico, extending as far south as Ecuador.

A. peruvianum, Klotzsch.—Another handsome species, well marked, with stout, ebony-black, glossy stipes, and large arching fronds, from 1 to 3 feet long, broadly ovate in form, simply pinnate or sometimes divided at the base. The pinnæ are large, trapeziform, taper-pointed, rounded at the base, with the margins lobed or finely toothed, of a very deep shining green colour. Native of Peru. Known and named for many years, but of comparatively recent introduction, and certainly it constitutes one of the most effective stove Ferns in cultivation, and no collection should be short of it.

A. princeps, Moore.—A charming species. It produces large arching fronds, from 1½ to 3 feet long, deltoid in form, tripinnately divided, with the final divisions fan-shaped, wedge-shaped at the base, and the outer margin lobed, of a rich green colour. It is a very noble-looking species, with a great width of frond and distinct appearance, approaching *A. speciosum* and *palmatum*. A most effective plant for all, but especially for exhibition purposes.

A. Seemannii, Hook.—A native of tropical America, occurring in Brazil, Veraguas, and Guatemala. Very distinct in appearance, and comparatively rare under cultivation. It produces beautifully arching fronds from 1 to 2 feet long, and from 6 to 8 inches broad, ovate-oblong in form, simply pinnate or rarely branched below, the terminal pinna the largest. The pinnæ are 3 or 4 inches long, on slender, black, polished stalks, ovate acuminate, unequally sided, cordate on one side of the base, with the margins finely serrated, when young of a pale reddish colour, changing to deep green in a mature condition. The pinnæ are perhaps larger than those of any other species, and are very effective upon the slender petioles.

A. speciosum, Hook.—This is a very lovely Fern, although inclined to be deciduous, but if kept in heat there are generally some fronds on all the year. It produces large, arching, tripinnate, deltoid fronds from 1½ to 3 feet long, and from 9 to 15 inches across

the base, with dark polished stipes and rachises. The final segments are large, semicircular or cuneate, shortly stalked, the upper margin deeply lobed, the lobes being again cut, of a pale green colour, the upper surface covered with short pubescence. Native of tropical America, occurring in Peru, Brazil, Bolivia, &c. Of comparatively recent introduction, but it is highly esteemed.

A. tenerum, Swartz.—However much I admire *A. farleyense* and other varieties which may have emanated from this, I still regard this as one of the most graceful of all the Maidenhair Ferns, and think it should be represented in all collections of stove Ferns. It produces fronds from 1 to 4 feet long, three or four times divided; the final segments cuneate or rhomboidal in outline, the outer margin deeply lobed, on short stalks of a light green colour, with a rather thin texture. The stipes and rachises are blackish and glossy, erect, while the fronds are prettily drooping. Plants of all sizes are most suitable for all decorative work, and as a large specimen it is very effective even as an exhibition plant.—T.

(To be continued.)

FRUIT FARMING.

YOUR correspondent, "A Fruit-Grower," in his excellent article on "Fruit Farming and Jam," at page 100, is quite correct in his statement as to the vast quantity of valuable dessert and culinary Apples which are annually converted into cider in this county (Herefordshire). Many of your readers, no doubt, would scarcely credit that Ribston Pippin, Blenheim Pippin, Downton Golden Pippin, King of the Pippins, and similar choice varieties all share the same fate. Not a few persons will doubtless exclaim, "What a shame!" But your correspondent has explained why the farmers resort to this course. The excessive railway rates are the chief cause, closely followed by the exactions of dealers and middlemen. It is time something was done to relieve the farmer from these exorbitant charges. With regard to salesmen and middlemen, large growers should do as some of the Kentish fruit-growers do—viz., attend the markets themselves and sell their own productions; they will then know exactly what they realise and save the commission, and not unfrequently make a higher price than a salesman would.

Until the railway rates are considerably reduced farmers in these parts are not likely to cultivate Apples for market to any great extent, cider-making pays too well for that; and here I would draw your correspondent's attention to a slight discrepancy in his statement. He says, "It takes on an average a bushel of Apples to make a gallon of cider." He has evidently been misinformed on this point, as 200 gallons of Apples will make 100 gallons of cider of good ordinary quality. This is a fair average. Many thousands of bushels of Apples have been sold during the past autumn at 1s. per bushel of ten gallons, so that the fruit necessary to make 100 gallons of cider has cost £1; add to this the usual charge for making—viz., 5s., and then selling the cider at 6d. per gallon, it surely leaves a fair profit. One shilling per bushel may be considered very low, but the crop was so enormous last season that they paid very well even then. Many a cottager's rent is annually paid by the product of his Apple trees; and at the present time many landowners find great difficulty in letting their farms where there are no good Apple orchards upon them, but have little difficulty in doing so when they promise to plant new orchards or renovate the old ones. The farmers find it in every way better and cheaper to give their men cider in preference to beer.

I know one gentleman who plants annually 500 trees of King of the Pippins, chiefly for cider-making, and he maintains there is no variety better suited for the purpose. The great advantage in planting such sorts as King of the Pippins, Downton Golden Pippin, or Blenheim Orange in large quantities, is worthy of note, as some seasons they will pay much better to send to market than they will to make into cider, even under the present adverse circumstances; whereas if the ordinary cider sorts are planted, they must be made into cider or wasted, as but very few of them are of any value either for dessert or culinary purposes.—H. R. ILLMAN, Hereford.

PRUNING ROSES.

ON page 15 I read with a little surprise the following—"All such as are growing in sheltered positions, if pruned at once, will in all probability afford abundance of early blooms." I presume this is meant only for garden Roses, and that no one would think of treating his exhibition plants to this early pruning, as, if not absolutely destroyed by such a March as that of 1883, they are certainly damaged, and in many localities the advice, however, is given for "sheltered positions."

The next paragraph, however, is to me quite incomprehensible, and

utterly opposed to my own experience. It runs, "Maréchal Niel and the Banksians require similar treatment, both flowering at every joint throughout the strong growths formed during the previous summer." Maréchal Niel certainly does flower at every joint of these long strong growths, but most growers, I fancy, would prefer its waiting to put forth its shoots till later. It is all too prone to start, and the pruning helps this forward; but as regards the Banksians I can only ask myself, Is it possible that in different localities they should act so differently? I have never seen a Banksia Rose bloom on the joints of these long vigorous shoots; quite the reverse. It is essentially on the small growth no larger than a crow-quill that the Banksia blooms at every joint. Never have I seen a bloom on one of these 8 or 10-foot shoots of the previous year, unless it may be on small shoots of six or eight joints growing from them, and this smaller growth not of the present year. The paragraph continues, "Thin out these growths and all spray." Now, if by "spray" is meant the small shoots from 1 to 2 feet long, these are the very shoots I should preserve if I wanted my Banksia to bloom. If a Banksian, white or yellow (the latter is the stronger), be planted in good soil, say against a house, it will probably run up some 14 or 20 feet high before any flower is seen. If it be liberally treated to the knife it will be many years before a flower is seen; but if allowed to have its own way, if the "spray" be only dealt with so as to allow sufficient circulation of air, there will then be abundance of bloom, provided the tree and the knife are almost strangers. A Banksia likes to grow somewhat wildly, and where room can be spared it well repays having its own way and plenty of space.—Y. B. A. Z.

[The writer of the controverted sentence does not say gross unripened shoots of Banksians will flower, but with him all firm strong growths from 1 yard to 2 yards in length produce strong trusses at every joint. Spray will flower, but he prefers cutting this away in order to secure abundance of stronger wood, which, well ripened, enables him to cut basketfuls of better blooms.]

"I PRUNED my Roses early (March 3rd) last year, and never had better blooms in spite of the severe snowstorm and bitter weather which set in immediately after. This year, again, I have now (February 29th) finished pruning in sheltered situations, and I fully believe that our Rose trees suffer less from being pruned than they would do if allowed to weaken themselves too long by such luxuriant growth as mild seasons induce. In pruning early care must be taken not to cut back too hard. Roses in exposed places and newly planted trees are better left another two or three weeks.—A. M. B."

PROTECTING THE FLOWERS OF FRUIT TREES.

THE time being at hand for taking action in this matter, a few remarks respecting the next best material to glass for this purpose, and the manner of applying it, may be acceptable to some readers. To these I would say, Obtain No. 5 hexagon shading, which is made in widths of 54 inches and 100 inches to suit high and low walls, and which is the best and most lasting material that I am acquainted with for this purpose. Having obtained the desired number of yards for covering the respective lengths of wall, divide it by 10 feet, marking the lengths from top to bottom on the entire piece with a straight-edge and piece of charcoal as the measuring is proceeded with, commencing at $2\frac{1}{2}$ feet from the end, and over each mark thus made sew a piece of strong inch-wide tape the same length as the width of the shading. In these (commencing at the bottom and finishing at the top) with needle and thread securely fasten the necessary number of three-quarter-inch brass rings 1 foot apart, and the use of which will be explained presently. This done, stitch a ring on to each bottom end of the cloth, and another $2\frac{1}{2}$ feet along the bottom from these, after which one should be sewn on every 5 feet the entire length of the cloth, and the latter is then ready for securing to the woodwork, and with the erection of which we shall at once proceed.

The first step to be taken in this direction is to obtain the necessary number of poles from the woodman. These should be about 3 inches thick at the top and 4 or 5 inches at the bottom, and sufficiently long (measuring from the top of the cornice or projecting course of brick) to allow of 10 or 12 inches of the thick end being let into the ground 18 inches or 2 feet from the base of the wall, the first and last poles being placed in $2\frac{1}{2}$ feet from the end of the wall, and all the others at 5 feet from pole to pole, and secured at the top with screws to forked holdfasts driven into the wall three courses below the coping, and projecting therefrom 5 or 6 inches. But before putting up the poles the tops of the latter should have a piece half an inch thick and 3 inches long cut off the inner side with the saw, so that they may rest steadily against the projecting brick, and the same depth and 1 inch thick should be cut off the outer side, on which side is screwed a stout strip of iron, rounded on the outside, 12 inches long, the top $2\frac{1}{2}$ inches (above the top of the pole) being made with a shoulder, and to take a nut and washer. Between the top 3 inches of the strap (which is an inch wide and level with the top of the pole) and the latter is a space of 1 inch for the reception of strips of deal board 3 inches wide, 1 inch thick, and

from 15 to 20 feet long, and halved about 3 inches at the ends for screwing together.

These strips, to which the cloth is to be fastened with small tin-tacks, should be furnished with pulleys—first at $2\frac{1}{2}$ feet from the end, and afterwards 10 feet apart, and between them a hook should be screwed on to the board and furnished with a loop for securing the cloth when raised. When the cloth is being put up pass a piece of sash-line (in length a few feet more than twice the width of the cloth) over each pulley and through the series of rings previously mentioned, fastening it to the bottom one, thus completing the mode of raising and lowering the cloth. When the latter is down means must be provided for securing it in that position during the night. This may be done by driving a hook well into the wall at each end of the cloth, and as far down as the latter will reach, and one into each pole sufficiently low to secure the rings with which the bottom of the cloth is furnished to. The next and last step to be taken in this operation is to place wide boards, having square ends and a piece nailed across one end to overlap the joints, and in the centre of which boards and 5 feet apart holes have been previously made for the bolts attached to the top of the poles to go through, on top of the projecting course of bricks and the strips of board supporting the cloth, then apply the washer and nut, and the erection of a substantial fruit-blossom protection, which is easily put up and taken down, is completed, and which, if put away and kept dry when not in use, will do good service for fifteen or twenty years.—H. D. W.

HARDY PLANT SYNONYMS.

I THINK that "Practical" has misunderstood my motive in giving a list of synonyms. Having for some time kept a list of the different names under which common plants are received for my own especial benefit, it occurred to me that if published, and properly supplemented by those having more experience in hardy plant nomenclature, it might prove useful, and, indeed, be the dawn of a new confidence between buyer and seller, and also those wishing to exchange. I aimed at no more than running the pseudo names under one standard heading, taking the foremost establishment for my pattern. How *Achillea serrata* can be confounded with *A. Ptarmica* I will leave "Practical" to follow up, as I have tried and failed. But as regards *Campanula lamiifolia* and *C. alliariaefolia*, I fear "Practical" does not know the cultivated plants under these names. I have always followed Decandolle where it was possible, and I find that even in a wild state, and although he describes them both in his "Prodromus," he says in a footnote that they are probably the same.

Then as to the *Androsaces*, *A. coronopifolia* (Andr.) we know as the old garden name for *A. lactiflora* (Fisch), which I find to be the same as *A. septentrionalis* for all garden purposes, after cultivating the plant for some years. The extreme varieties are distinct enough, but in about a dozen plants from different localities I convinced myself of a gradual change into one another. If "Practical" explains the difference between the *Campanulas* and the *Androsaces* he will, I am sure, receive the thanks of all.—SPECIALIST.

GLAZED FLOWER POTS.

AT page 143 of the Journal, Feb. 21st, Mr. Henderson, after reading Mr. Thomson's interesting article (page 101) on glazed flower pots, suggests painting ordinary pots. About ten years ago I wanted to have the conservatory in extra good condition for a particular occasion. So, not having any of the fine glazed pots, I had them all painted with red enamel as near the shade of the pots as possible. They looked very well, and the plants grew well in them; but—and this is my reason for penning these remarks—before the season was over the paint gave way and the lime began to show through the pots, much disfiguring them, so that I was glad when the last traces of the paint were scrubbed off. I had some hundreds done, large and small, and the result was such that I did not again try to imitate the glazed pot.—G. R.

HEPATICAS.

THE various plants constituting this genus, or rather section of the genus *Anemone*, as it is now considered, are some of the brightest and best of our early spring flowers, and have many and varied claims on the interest of all lovers of hardy plants, coming into bloom as they do with the Snowdrop and the Winter Aconite, and giving bright promise of that wealth of floral beauty which the later months bring to our gardens.

This section, which is well marked, contains four so-called species, which are all now in cultivation—viz., *H. acutiloba*, *H. americana*, *H. angulosa*, and *H. triloba*; the two latter being much more generally known and cultivated than the former, *H. triloba* especially, with its numerous varieties. All of them are of easy culture and require no special position, being almost equally at home amidst the smoke and dust of a London garden or in the pure air of a country village. They thrive best, however, in a cool rich stiff loam, although not by

any means objecting to a soil containing a considerable quantity of peat, such as may be found around a *Rhododendron* bed; and, unlike many plants, will thrive under the shade of trees and amongst low-growing shrubs if not too closely planted. They should be divided carefully at the end of the flowering season—viz., about the second week in April, and replanted deeply, care being taken to put the roots well down and not cramped in a mass, as is too often the case. A slight mulching of moss around their crowns will be found very beneficial, as it checks evaporation considerably, and thereby preserves a comparatively even temperature. These plants should never be moved except when absolutely necessary, for although they will flower freely the following year, yet the difference between plants which have been allowed to remain in the same position for several years and those which have been recently disturbed is very great.

Most of the single varieties produce seed freely, which, if sown immediately it is ripe, will germinate early the following spring, and produce many shades of colour between white and deep blue or pink, the different forms shading into each other in such a manner as to set distinction at defiance. Unfortunately many of these lovely seedlings are not permanent, and gradually revert to the bright blue of the type. A short description of the various forms which have become fixed, and may be purchased at most hardy plant nurseries, will show the range of colour which may be obtained at this season (February 13th) from these plants alone.

H. acutiloba.—A stemless perennial, with numerous acutely heart-shaped leaves split into three lobes, which are very acute and not serrated. Flowers blue, solitary, on smooth stems from 4 to 6 inches in length, produced in great profusion in March. A native of the United States, usually found in copses and the less dense portions of forests. There are two varieties—viz., *alba*, distinguished only by its colour, and *fragrans*, said to be sweet-scented but in other respects identical with the type.

H. americana.—A reputed species, flowering at the same season as *H. triloba*, and so far as I have seen only an American form of that plant not sufficiently distinct for general purposes.

H. angulosa.—By far the finest plant in the section, growing to fully twice the size of *H. triloba* in all its parts, and easily distinguished from all others by its leaves being five instead of three-lobed. The leaves are produced on stems from 6 to 9 inches in length, five-lobed, the lobes being coarsely toothed. The flowers are of a bright sky blue, often as large as a half-crown, with black anthers. A native of Transylvania. This species prefers a soil containing considerably more sand than any of the others, and is decidedly the finest of all very early spring-flowering plants, flowering, as I have frequently seen it in the north of England, from the 9th to the 16th of January, and often producing a succession of flowers for two months.

H. triloba (*Anemone Hepatica*).—An old and favourite inhabitant of our gardens. Leaves cordate, three-lobed; the lobes ovate, acute, entire, but not so decidedly acute as in the first species. The flowers are blue, solitary, on hairy stems 3 to 6 inches in length, with a three-leaved involucre, very numerous, usually lasting from February to April. A native of most parts of Central Europe in the woody districts on the flanks of mountains. As far as colour is concerned this is a most variable type, in other respects very constant. This tendency would no doubt be worked upon to good effect if these plants were taken in hand by the hybridiser. Most of the varieties being named according to colour, and not needing any special culture, it will suffice to mention their names: blue, single and double (this latter at present the rarest of the varieties, and an exceedingly good plant; lilac, single; pink, single; red, double and single; major, a fine and strong-growing light blue form; Barlowi, a very good single mauve variety; splendens, the largest and brightest red of any; and last but not least the lovely *alba* and *nivea*, both single white, the former having red anthers and the latter white ones. By the way, why could not the nurserymen adopt these two last names, which are published in authoritative works, and not such titles as *Hepatica triloba alba staminibus rubra*, and ditto ditto *alba*? Such names are calculated to disturb the repose of ordinary mortals.—G. GUTHRIE.

THE BEST MEANS OF PROTECTING PYRETHRUMS FROM SLUGS.—Some time ago I had a collection of thirty varieties of those beautiful and very useful flowers. Unfortunately all our beds and borders are, with a few exceptions, edged with Box, and most people know what a refuge and safe retreat this is for slugs and other garden pests. Hardly a particle of foliage was allowed to appear, and the result was my collection dwindled, and, being unable to ripen any foliage, the roots finally died with a few exceptions. "Whatever men dare they can do," and I was determined not to be foiled, so I had two dozen more last November

of different varieties I need not now name, and have happily succeeded in completely baffling the depredators by means of sifted coal ashes. I surrounded the rising foliage with this, and gave up lime, soot, and the various other expedients I tried, and so far I am rewarded with the fullest success, which I beg to commend to any of your readers so troubled.—W. J. MURPHY, *Clonmel*.

WE are informed that in addition to the fortnightly meetings of the ROYAL HORTICULTURAL SOCIETY at South Kensington, S.W., arrangements have been made with the Council of the International Health Exhibition to hold monthly exhibitions of fruit and vegetables in the conservatory on the following dates, when prizes amounting to £1000 will be offered for competition. May 27th, June 24th, July 22nd, August 12th (Cottagers' Show), August 26th, September 23rd, and October 14th and 28th. The schedules are now being prepared, and may be had on application.

— IT has been recently stated on good authority that the average annual CONSUMPTION OF POTATOES IN GREAT BRITAIN is 4,000,000 tons, representing at 5s. per cwt. £20,000,000 sterling. Of this quantity about 200,000 tons, or a twentieth, is imported. In 1882 the British Potato crop covered about 541,000 acres of land.

— IN reference to the report of the NOTTS HORTICULTURAL AND BOTANICAL SOCIETY'S MEETING on page 167, Mr. Jenkins states that the splendid examples of *Clematis indivisa lobata* mentioned were contributed by Mr. Meadows, gardener to J. C. Cox, Esq., Basford, and not by Messrs. Barratt. Our correspondent further observes: "It is one of the most lovely winter-flowering cool greenhouse climbers in cultivation, its requirements being simple—namely, plant it out in a fairly deep and good ordinary vegetable soil, train it to the roof at first, and afterwards allow it to ramble at will."

— WE have received from Messrs. Cassell & Co. the first part of the "ENCYCLOPÆDIC DICTIONARY," which they are about to issue in monthly parts. It will embrace all the words in the English language, with a full account of their origin, meaning, pronunciation, history, and use. It will also include all Scotch words now in use, with their several significations re-investigated, re-classified, arranged afresh, and illustrated by examples. We do not know whether to admire most the marvellous labour which must be expended on the production of such a work, of which the part before us is an example, or the great accuracy, painstaking, and research which have combined to produce one of so great value. It is copiously illustrated with excellent woodcuts of technical subjects where these are required to illustrate the text. It is a great undertaking well carried out, and will be when completed a necessity in the home of all English-speaking people.

— "FIR TREE OIL: AN INSECTICIDE FOR PLANTS AND ANIMALS," by Mr. E. Griffith Hughes of Manchester, is the title of a small pamphlet before us, the object of which is to show the efficacy of the oil in question, which is, perhaps, not disputed by many persons who have used it judiciously.

— WE cite from the above pages the following time-honoured paragraph relative to WIREWORMS AND LINSEED CAKE:—"Their hardy nature renders them impervious to the action of all known insecticides, but one of the best methods of destroying them is by scattering over the ground and raking into the soil a good supply of ground linseed cake, upon which they readily feed and soon burst. The writer has found this mode of dealing with them very effectual in preventing their attacks upon annuals which were threatened by the grub." This is the first time we have had the direct evidence of a writer that he has found the above result. We have tried to destroy wireworms in the manner indicated, but always failed; and we could tell of a clergyman who mixed far more linseed cake than is usually recommended with soil, placing the mixture with a number of wireworms in a cask, keeping them there for many weeks or perhaps months. The experiment we inspected, and never saw wireworms in finer con-

dition and apparently more contented with their fare. There were hundreds of them, but so far as could be ascertained not one "burst." Perhaps they were of a hardier kind than those referred to by old authors and Mr. Hughes.

— THE LIVERPOOL HORTICULTURAL ASSOCIATION'S SPRING SHOW will be held in the St. George's Hall on Wednesday, March 19th. Prizes ranging from £3 to 5s. are offered in forty-six classes for bulbous plants, miscellaneous forced plants, Orchids, groups, and bouquets.

— MR. J. MALLENDER sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, FOR FEBRUARY, 1884. Total duration of sunshine for the month 58·7 hours, or 21 per cent. of possible duration. We had seven sunless days. Total rainfall, 1·29 inch. Rain fell on seventeen days. Mean temperature of month, 41·3°. Maximum on the 13th, 54·4°. Minimum on the 29th, 21·6°. Maximum in the sun on the 27th, 99·0°. Minimum on the grass on the 29th, 15·2°. Warmest day the 13th; mean temperature, 48·2°. Coldest day the 29th; mean temperature, 31·0°. Mean temperature of air at 9 A.M., 40·4°. Mean temperature of soil 1 foot deep, 41·1°. Number of nights below 32° in shade, four; on grass, thirteen. Wind mostly S.W.; average velocity, 12·8 miles per hour. The velocity exceeded 400 miles on seven days, and fell short of 100 miles on three days. The temperature was lower than in January, the rainfall less than in any February since 1878, and the sunshine less than last year, but more than in the two preceding ones. The temperature of the soil was higher than in the last two years, the vegetation being very forward.

— ON Saturday evening last a highly instructive and interesting lecture was given to the members of the LIVERPOOL HORTICULTURAL ASSOCIATION in one of the lecture rooms of the Free Library by Mr. Robert Wilson Ker, of the Aigburth Nurseries, on "New and Rare Plants." Mr. Richardson, Curator of the Botanic Gardens, presided. The lecturer gave a graphic description of his visits during the past twenty years to the principal plant-raising establishments in this country and the continent, and described, with the aid of a number of beautifully coloured drawings, most of the latest novelties introduced to the plant-admiring public. After an agreeable discussion, taken part in by Messrs. White, Ranger, and Cox, the meeting was brought to a close, a hearty vote of thanks being awarded to the lecturer, and also to Mr. Richardson for presiding. The next lecture of the session takes place on the 15th inst., when a well-known cultivator and exhibitor, Mr. Blomily of Aigburth, will give his experience on the cultivation of *Eucharis* and the *Vallota*.

— THE "Science Monthly" for March contains a portrait of Sir Richard Owen, with full account of his scientific labours. A series of papers upon "The Antiquity of the Earth" is commenced; also upon the "Recent Phenomena in the Sky." "Lessons from Common Plants" are continued, and there are contributions upon the "Extinct Volcanoes of the British Isles," and "Ferns and Lichens as Food Plants."

— WE learn that the NATIONAL CHRYSANTHEMUM SOCIETY intend issuing an official catalogue of Chrysanthemum names, and as this work is to be entrusted to a committee of experts it will undoubtedly be reliable and useful. The Honorary Secretary, Mr. W. Holmes, states that since they have adopted the title "National" they have every reason to be pleased with support they have received, which will no doubt be further extended if such useful work as that promised is continued.

— REPORTS of a SEVERE SNOWSTORM were received in London on Monday last from various parts of England and Scotland. A Dumbarton telegram stated that by far the most severe snowstorm which has visited that district for some years was raging on Monday morning. Snow began to fall about four o'clock, and it soon became from 4 to 5 inches deep. Outdoor labour was entirely suspended. In the neighbourhood of the metropolis the weather has been very cold, accompanied by continuous rain, but this will have the effect of checking the fruit blossom, which is very forward in the suburbs, Pear trees being much advanced.

— THE FOURTEENTH BRISTOL SPRING EXHIBITION is announced to take place in the Victoria Rooms, Queen's Road, Clifton, on March 19th and 20th, when liberal provision will be made for the exhibition of bulbs and miscellaneous forced plants in flower, together with flowers, bouquets, and fruits. Special prizes are offered in twenty classes, the donors being gentlemen residing in the neighbourhood and supporters

of the Society. A silver cup value four guineas is offered as the first prize in an open class for the best collection of plants arranged in a space of 12 feet by 7 feet. The Treasurer, Walter Derham, Esq., also offers three prizes of three guineas, two guineas, and one guinea respectively for collections of eighteen Hyacinths and twelve Tulips.

— "A LECTURE ON ROSES: THEIR HISTORY, CULTURE, AND EXHIBITION," by Samuel Eyre, has been sent to us, printed in the form of a small pamphlet. The lecturer is evidently an ardent lover of the Rose, and has given the outlines of its culture concisely. Cultivators are counselled to "avoid artificial manures; they are injurious and dangerous, and experienced growers never recommend them." We think his favourite author, Canon Hole, has recommended bonemeal, and we know that many Roses have been improved by its application, as they have been by other fertilisers when judiciously applied. The pamphlet is published by Mr. M. H. Miller, *Times* Office, Leek.

— THE usual fortnightly meeting of the MANCHESTER HORTICULTURAL IMPROVEMENT SOCIETY was held at the Old Town Hall last week, Mr. B. Findlay in the chair. The subject of the evening's paper was "The Life History of Flowering Plants," by Mr. G. Lunt, Superintendent of Stamford Park, Ashton-under-Lyne. Aided by a large number of specimens and diagrams the lecturer traced the whole of the processes by which the spores in some cases, and seeds in the greater number, gradually develop and progress, aided by nutriment from the soil as well as from the air, and clear light and sunshine, until leaves, buds, and flowers are formed; and then the various agencies that are then at work by which the fertilising process is carried on, so that seeds again may be perfected and the species or variety permanently established. The stems of plants and trees were treated upon and classified. The structure of leaves, the arrangements of the divisions of the flowers in many species and genera, were also described. The last meeting of the session will be held on Thursday, March 6th, when the annual report will be read.

— A CHANGE in the treatment of the ADIANTUMS AND GYMNOGRAMMAS at Kew has been recently adopted, and appears likely to lead to good results. The span-roof house there runs nearly east and west, and at the west end the sunny side has been hitherto devoted to the Gymnogrammas and the shady side to the Adiantums. Neither have made really satisfactory progress. The Adiantums have often been too weakly, and the fronds of the Gymnogrammas have displayed that unpleasant habit of shrivelling like the *Cheilanthes* and *Nothochlænas*. The fact is that Gymnogrammas, although usually described as sun-loving Ferns, require in such positions exceedingly careful and frequent attention in watering, or they speedily suffer, often to an irremediable extent. Again, as regards the Adiantums, in some market establishments the plants are grown in unshaded houses, and make sturdier and more enduring fronds under such circumstances than when in the darkened houses commonly accorded to tropical Ferns. Acting upon these facts the positions of the two genera have been reversed, the Adiantums being placed in the sunny side, and the Gymnogrammas in the shade, an improvement in their condition being discernible already. Further, the Adiantums have been placed in shallow pots or deep pans, thus avoiding the employment of so great a mass of compost for large specimens.

— THE schedule of the BASINGSTOKE HORTICULTURAL SOCIETY gives the dates of their Shows for the present year as August 19th and November 25th and 26th, the former to be held at The Goldings and the latter in the Volunteer Drill Hall. This Society appears to be flourishing, for a favourable balance of £26 is announced as a result of last season's receipts and expenses. At both Shows the classes are numerous, but the prizes are rather small.

POINSETTIA CULTURE.

I AM disposed to agree with your correspondent, Mr. C. H. Stephens, on page 60, in propagating Poinsettias in heat after potting, transferring them to a cool frame, and afterwards to an intermediate house, previous to placing them in the conservatory or stove. His method is carried out at Basing Park, which place has given me not only the finest examples of *Poinsettia pulcherrima* and *plenissima*, the bracts from 16 to 22 inches in diameter, and the plants 18 inches to 2½ feet high. In growing most softwooded stove and greenhouse plants as many as thirty two and three-light frames are used for this purpose. The result is that summer reigns in the conservatory and plant houses all the year round.

I think in the south the culture of Poinsettias might be further extended to advantage, and I feel sure many in the north would not regret trying them fairly. Nevertheless I think Mr. J. Saunderson on page 106 is correct in recommending a little more heat; but in that case a good

heated pit frame would be more useful, and is far preferable. Air and light can be more freely given.—A FOREMAN.

I BEG to offer a few remarks, as suggested by your correspondent Mr. C. H. Stephens, on our mode of cultivating this most useful and showy winter decorative plant, hoping they will be useful to some of your younger readers. When the plants have flowered, or rather after the bracts fall, they are placed in a warm house and allowed to rest until about the end of April, when they are watered, and a little extra heat employed to induce them to break. As soon as the young shoots have made three or four joints they are taken off with a heel and inserted singly in thumb pots, using a compost of equal parts of loam, leaf mould, and sand, then plunged in a propagating frame. After they are rooted we place them in an intermediate house, where they are grown during the summer along with other useful winter-flowering plants, such as Begonias, Sericographis, and Thysacanthus. The young plants are carefully attended to as regards watering and potting, 7-inch pots being the largest size we use.

After the first shift we employ a larger proportion of loam, with a little peat and old Mushroom-bed manure. The plants are kept near the glass, ventilating on all favourable occasions, lightly shading them from midday sun. When they have completed their growth and commenced to form bracts we place them in the stove, and water occasionally with soot water. As the heads become fully developed they are taken into the show house, where they give a grand display for fully three months. We have plants in bloom now that have been so since the end of November. By this method we have had heads over 20 inches in diameter. We confine our stock to young plants. It must be stated that we apply a top-dressing once or twice of Ville's Normal manure, which invigorates the plants, giving the leaves a rich green hue, and I think the bracts last considerably longer. We find it beneficial for all softwooded plants.—J. SAUNDERSON.

PEACH TREES—EXTENSION v. RESTRICTION.

I AM much interested in the extension of Peach and Nectarine trees, but I have never yet seen the system properly defined. If I am not mistaken Mr. Simpson claims credit as being the author of the extension system "pure and simple," and perhaps he can throw some light upon the subject. It appears to me that extension may be defined in much the same way as an eminent doctor defined "moderation" when speaking on the temperance cause. The doctor on asking for a definition of the term which had been advocated by a certain society, said his own was "anything between a glass and a barrel;" so with extension, it is anything between 1 yard and 20. I am perfectly aware that it is not difficult for a Peach and Nectarine tree six, seven, or eight years to have a spread of branches of 25 to 30 feet on each side of the main stem. If a tree had been allowed to extend and fill that amount of trellis in the time indicated it would be called the extension system "pure and simple." Would a tree of this description yield the same lengthened succession of fruit as two or three trees would do of different varieties if they filled the same space? Suppose a cultivator has a house 25 feet long, and a tree is planted in the centre and allowed to fill the whole house, grown on the extension system, how can the extension system be further carried out? As far as I can see extension ends, and a restrictive system must follow. Mr. Simpson, although he advocates extension, is following a system of restriction, for he says "These have had to be shortened back, and the trees root-pruned more than once to restrain over-luxuriance." What is this done for, if not to restrict the trees to a certain space, or else why not allow them to extend? If trees are root-pruned to prevent them extending, restriction commences and the extension system ends.—A WORKING GARDENER.

ELECTION OF CARNATIONS AND PICOTEEES.

THE ELECTORS' RETURNS.

[The names of the raisers of the varieties in the following lists have been given in the previous returns.]

From Mr. E. ADAMS, Swalwell, Gateshead.

CARNATIONS.

Scarlet Bizarres.

Admiral Curzon

BAUERA RUBIODES.

An evergreen greenhouse shrub, having somewhat slender erect branches, the young shoots having crimson bark and whitish hairs, the leaves arranged in whorls of five or six, which give to the plant a very elegant appearance. The flowers are produced from the base of the whorl of leaves in profusion, being stellate in form, about half an inch across, and of a pale rose colour. It flowers for several months in the year, generally in the late winter and early spring months, but is more or less a continuous bloomer, and being of free growth soon forms a good specimen. It does well under the treatment given to Australian plants generally, and in a compost of loam, peat, and leaf soil, with a free admixture of sand. Being of straggling habit it should be cut in after flowering, and potting deferred until it has started into free growth again. In a dry atmosphere it is subject to red spider, but that can be kept under by free syringing on fine days.—G. A.

[A figure of this plant was given in our pages, July 5th, 1883, with historical and descriptive notes.]

CACTACEOUS PLANTS.

PELECYPHORA, Ehrenberg.

(The Hatchet Cactus.)

In a botanical point of view this genus and the following one are the most interesting in the family. They are both monotypic—that is, contain one species each, and are remarkable for certain structural peculiarities that have attracted much attention from students of the order. Pelecypophora is closely related to the Mamillarias, having a short cylindrical stem, covered with mamillæ or tubercles of a flattened form, and which have

been supposed to bear some resemblance to a hatchet, as the generic name implies. At the apex, however, in the place of the spines of the Mamillarias are two rows of flat horny scales, which overlap like the tiles of a roof, and have been not inaptly compared to the scaly back of a woodlouse, to which character the specific name refers. The flowers are borne near the summit of the stem 1 to 1½ inch in diameter, consisting of several series of sepals and petals, numerous stamens and stigmas.

In culture and propagation *Pelecypora* is similar to the more delicate Mamillarias; it requires a sandy soil, good drainage, and very careful supplies of water. Offsets are seldom produced, and the readiest method of increasing it is by seeds, which germinate freely in moderate heat, and numbers of plants have been so raised in this country as well as on the continent.

PELECYPORA ASELLIFORMIS, Ehrenberg.—This, the only member of the genus, is a native of Mexico, where it was found by the brothers Tonel, associated with plants of the now discarded genus *Anhalonium*, which has

Fig. 37.—*Pelecypora aselliformis* var. *concolor*.

been already mentioned under the Mamillarias. The first plants imported to Europe were received at Berlin, but found to be dead, and Labouret relates that Ehrenberg raised the first living specimen from seeds found in dried fruits contained in the axils of the tubercles. The plants so obtained were described by the last-named author in 1843, though the flowers were then unknown. In 1858 Lemaire gave a full description and illustration of the plant in the *Illustration Horticole*, vol. vi., t. 186, which drew much attention to it, and several growers of Cacti obtained plants for their collections. Amongst English cultivators Mr. Justus Corderoy of Blewberry, Didcot, Berkshire, was especially successful in raising young plants from seed, and through him numbers were distributed throughout the country; indeed, he claims to have done what growers could never do before nor since—namely, sell plants of *Pelecypora* at 3s. each. Several of these seedlings he succeeded in flowering, and proved slightly different from Lemaire's plant in the colouring, the flowers of Mr. Corderoy's variety being uniformly rosy purple, while in Lemaire's plant they had an outer series of pale almost white petals. One of these specimens was submitted to Dr. Hooker, and figured in the "Botanical Magazine," 1873, t. 6061, under the name of *P. aselliformis* var. *concolor*. Though so interesting structurally, and pretty when in flower, this Cactus continues very scarce, and few collections now include examples of it. Fig. 37 is engraved from a photograph of one of the Blewberry plants, representing it of the natural size, a single tubercle being shown at the side.

LEUCHTENBERGIA, Hooker.

Few who were unacquainted with *Leuchtenbergia principis* would, at the first examination of a plant not in flower, think it was a member of the Cactus family; it is so entirely distinct from all the genera and species in outward appearance, and might be easily mistaken for an Aloe or some

relative of the Haworthias. A glance at the flowers would, however, be sufficient to indicate its true position in the vegetable kingdom, as the calyx is somewhat tubular with numerous lobes, the outer scale-like, the interior narrow and spreading, the petals being in two series, coloured like the petals, with indefinite stamens and numerous stigmas. The tubercles are triangular, about 3 to 4 inches long, crowned with several peculiar flattened ashy-grey spines that have a withered appearance, and vary in length from half an inch to 2 or 3 inches. These tubercles are arranged spirally round the stem, and, owing to their differing so much from the tubercles in *Pelecypora* and Mamillaria, they have been the subject of much discussion as to their true nature. The apparent difficulty of the matter has been increased by the fact that the flowers are produced near the apex of the tubercles and not from the axil, as in the Mamillarias. Respecting this point also there has been a divergence of opinion, some writers describing it as producing the flowers from the axils and others from the apex. Writing me upon this subject, Mr. R. I. Lynch, Curator of the Cambridge Botanic Garden, observes, "Lemaire in 'Les Cactées' ridicules the idea that the flowers of *Leuchtenbergia* are borne at the summit of the mammæ, but his information was untrustworthy. It does habitually flower from that position, as I have frequently seen. In some cases the flowers are produced near the apex of very little developed mammæ in the centre of the plant, and it would be easy to make a mistake as to the actual origin of the flower, as it is wedged in tightly by the other mammæ. Most flowers that I have seen were, however, borne quite clear of the centre." This is undoubtedly the fact, as I have seen flowers down in the centre as described, and, without removing them, it would be almost impossible to decide whence they sprung; while, on the other hand, Mr. Corderoy has sent me a sketch showing the flowers quite clear from the other tubercles, and close to the summit, as stated by Mr. Lynch.

These tubercles therefore appear to be of a compound nature, representing the fusion of petiole and peduncle similar to what occurs in *Helwingia* and *Erythrochiton*. Lemaire partly adopted this view regarding the mammæ of the three genera Mamillaria, *Pelecypora*, and *Leuchtenbergia* as metamorphosed leaves, the spines representing the veins of the leaves, in which opinion many careful observers agree. Le Maout and Decaisne describe them as "arrested buds," and would thus give them more the nature of branches, while others incline to the view that they are simple elevations of the substance of the stem similar to the ridges in *Echinocactus* and *Cereus*.

This is a rather difficult plant to grow satisfactorily, but it should be treated similarly to the Mamillarias as regards soil, and most carefully attended in the supply of water, as the slightest approach to excess will result in serious injury and probably the death of the plant.

LEUCHTENBERGIA PRINCIPIS, Hooker.—In 1848 an excellent figure of this plant was given in the "Botanical Magazine," accompanied by a full description by Sir W. Hooker, which is so graphic that it is here reproduced. "Our largest plant is a foot high, its main trunk erect, but crooked, as thick as a man's arm, clothed with the dense mass of persistent bases of old mamillæ, or perhaps rather of the withered mamillæ themselves, shrunk and reduced to a mass of closely pressed scales. Above they gradually become more perfect, at first short and truncated till the crown of the plant is clothed with perfectly formed mamillæ, resembling aloid leaves 4 or 5 inches long, glaucous green, succulent, triangular, truncated at the apex, and there bearing six or seven long chaffy, or almost horny linear or subulate flexuose scales, of which the centre one is about as long as the mamillæ, and the others form a whorl round the centre, are about 2 or 3 inches long, spreading, triangular. These appear to be after a time deciduous, for the lower withered mamillæ are destitute of them." In the further description of the flower the position is said to be "from the axil of a mamilla," but in the "Genera Plantarum" this has been corrected. The flowers are large, of a rich clear yellow tint, and are usually solitary, though in some cases two are borne on one plant at the same time.

The species is a native of Mexico, having been found near the Rio del Monte, and introduced to the Royal Gardens, Kew, in 1847. Like the *Pelecypora*, Mr. Corderoy has been very successful with this plant, and the engraving represents one from a photograph of eight plants, several being in flower, which he had taken some time since.—L. C.

(To be continued.)

ORIGIN OF EAST LOTHIAN STOCK.

In reference to the paragraph in your issue of the 7th ult. regarding the raiser of the East Lothian Stocks, perhaps a few words might not be inopportune about the raising and selection of these lovely plants.

About the year 1853, whilst at Traprain, I commenced a series of experiments in grafting with two varieties of Stocks, one variety known in East Lothian as Anderson's Stocks, and the other variety as Cape Stocks. After twelve years of almost incessant attention and labour upon them, I was so far successful as to select five distinct and hardy varieties of Stocks now known as East Lothian Stocks.

It may be interesting to your readers to know that during these twelve years of experimenting I raised with more or less success nearly thirty varieties, but on account of indistinct colouring, together with tender habit and inferior growth, I was compelled to discard all with the exception of the five varieties now in common cultivation.

I have often been surprised when walking through a garden to have pointed out to me what the gardener or grower called East Lothian Stocks, and to find the plants were not East Lothian Stocks at all, or, at any rate, of so inferior a quality as to be scarcely recognisable as such. The largest and finest collection of true East Lothian Stocks I have for a long time seen is in the nurseries of Messrs. Ormiston & Renwick.

My friend Mr. Thomson of Drumlanrig has all along taken a lively interest in the culture of the East Lothian Stock, and in him I have always found a warm sympathiser with my humble labours in this department of floriculture, as well as an enthusiastic admirer of this charming and valuable class of pot and bedding plants.—THOMAS CAMPBELL, *The Asylum Gardens, Melrose.*

CRINUMS.

CONTINUING my notes upon these plants from page 173, the following species are worth attention.

C. Careyanum.—Under the names *C. Moorei*, *C. Macowani*, *C. Mackenii*, *C. Makoyanum*, and *C. ornatum* what appear to be but slight varieties of one species are known in gardens. Botanically four of these should be distinct species; but so far as I have been able to ascertain the plants cultivated as such in gardens are wrongly named, being all of them forms of *C. Moorei*. The true *C. Careyanum* has a round short-necked bulb, and bears from six to ten leaves about 18 inches long, and a scape a foot high, bearing flowers about 4 inches in diameter with pale red-tinted segments. It is a native of Mauritius, and therefore requires stove treatment.

C. Moorei.—A well-known garden favourite, and is one of the finest of greenhouse bulbous plants. It is established out of doors in several gardens in this country and at Glasnevin. At Kew last year several plants growing in a sheltered border produced an abundance of flowers throughout the summer. This is the plant to which most of those under the name *Careyanum*, &c., in gardens really belong. In colour the flowers vary from almost pure white to deep rose. It is a native of Natal. By crossing this with some of the strong-growing many-flowered species some good results would most likely be obtained.

C. Commelyni.—Bulb 2 inches in diameter, short-necked, and bearing leaves 18 inches long and very narrow. The flower stalk is nearly a foot in length, and bears an umbel of four or five flowers, which are about 6 inches long, the segments being narrow and purple on the under side. A native of Para.

C. erubescens.—A common plant in tropical America, and long known in gardens here. It has an egg-shaped bulb with a short neck, and bears a large number of long narrow leaves, which terminate each in a long point. The flowers are borne in umbels of about half a dozen on stalks nearly 2 feet long, and are white or tinted with purple. There are several varieties of this species. It is a summer-flowering plant, and thrives in an ordinary greenhouse temperature.

C. giganteum.—A large-bulbed long-necked species, similar in habit to *C. amabile*. The flowers are produced on long-stalked umbels, varying in number from six to twelve in each umbel. They are pure white, and measure sometimes almost a foot in length, the segments being over an inch wide and lapping over each other similar to an *Amaryllis* flower. A delicious fragrance, good substance, and large size combine to make this *Crinum* one of the finest for large houses. It is a native of tropical Africa, and requires stove treatment and plenty of water during the greater part of the year. It flowers in summer.

C. latifolium.—A tropical, water-loving plant; and, moreover, is a somewhat variable species. The bulb is large, has no distinct neck, and bears numerous leaves, which are from 2 to 3 feet long. The flower stalk, which is produced from the side of the bulb, is about 18 inches in length, and bears about a score of white flowers, which are tinted with red. In form these flowers resemble those of the last-mentioned, but are not quite so large. A native of the warmer parts of India.

C. pedunculatum.—A large, thick-necked, and, for the size of the plant, small-bulbed *Crinum*, somewhat like *C. amabile* and several other large kinds. The flowers are pure white, and are produced in summer. At Kew it may be seen represented by several fine specimens which flower every year. A native of South Australia, and may be grown in a warm greenhouse.

C. scabrum.—A large-growing sort, with very long leaves, and flowers white striped with red, and very fragrant. One of the most beautiful species, and is a free grower and flowerer, producing about half a dozen flowers in an umbel several times during the summer months.

C. zeylanicum.—A large-bulbed species, with a short attenuated neck and leaves of a thin texture, which grow almost horizontally. The flowers are arranged in umbels of from twelve to twenty, and droop over, so that the apex of their almost tubular limb or overlapping segments looks downwards. These segments are white, with a broad band of red along each side. The flowers are very sweet-scented, and are borne during the winter.

C. Kirkii.—Similar in every point to the above. These about complete the list of garden kinds; a number of rare ones such as *C. Hildebrandtii*, *C. Balfourii*, *C. defixum*, and others grown

at Kew being as yet beyond the reach of horticulture. It will be seen from the characters of those above described that there is a wide range of variation in *Crinums*, and if the distinct and large-flowered characters of some of the unIntroduced kinds be considered, the value of the genus for garden purposes will be evident enough.

The cultivation of *Crinums* may be stated generally to consist of treatment usually adopted for bulbous plants. They all like water when growing, and those that do not lose their foliage for a portion of the year should never be dried off. The deciduous ones, of course, must be kept dry until they show signs of starting into growth again. A strong clayey loam, well drained, and mixed with wood ashes or crushed bones, is perhaps the most suitable soil for all *Crinums*. They should be potted firmly in pots of large enough dimensions to admit of their roots spreading somewhat. They require plenty of light. The most favourable time to repot them is directly after they have flowered.

For out-of-door species deep planting in a rich well-drained border, with protection from exceptionally severe weather, is all that the bulbs require. The fruits of *Crinums* resemble Oak apples in shape and size, and if placed in a warm dry atmosphere they will produce a bulb without the aid of either soil or moisture. I have had a fruit standing on a shelf near the fireplace where the atmosphere is always dry, and this produced a fine bulb in the course of about two months. The development of this bulb is very interesting and is one of those singular

Fig. 38.—*Leuchtenbergia principis* (reduced).

instances of metamorphic vegetation which in the fruits of *Amaryllids* are of not unfrequent occurrence.—W. W.

AN EXPERIMENT WITH POTATO MANURES.

LAST year I experimented on a Potato plot with a series of manures, employed both singly as well as in combination. The experiment was undertaken to satisfy myself on some moot points raised in the *Journal* as well as in other publications, and though the extremely dry weather during six weeks of the summer rendered some of the experiments nugatory, they were on the whole extremely interesting and satisfactory. With some special manures, about twenty-four separate manures or combinations of manures were tried. Those which the drought hindered me from carrying out were a series in which potassic and phosphatic manures were applied when the crop was planted, it having been intended to add sulphate of ammonia and nitrate of soda at a certain stage of the Potato growth, and to mark the effect as compared with compounds in which the latter two agents were included and distributed when the Potatoes were planted. When rain did come growth was too far advanced to apply these nitrogenous bases.

I may explain that our soil is what is termed "light," but through long cultivation it has been brought into a good condition. Farmyard manure is freely employed, though we generally take three crops for one application of manure. I wanted to find out how far "artificial" manures benefited Potatoes on our soil; which was the best form in which to employ potash thereon; and the combination which gave the largest crop. It is not necessary to go into the whole experiments in detail, it will be of more interest to show how the largest crop was obtained,

with a note on a few of the other experiments, in order to show by results the effect of a given manure on a particular soil. I will not go so far as to say that the same results will follow under conditions which may appear similar in other gardens, but it may be expected that such would be the case; and again in recommending these manurial agents it must not be supposed that farmyard manures are thereby, or in any sense, thought less highly of than before. The simile is not quite an accurate one, but artificial manures when applied to fertile soils may be compared to the spur to a well-fed and willing horse, with this difference, that whereas the spur does not add to the staying power of the steed, artificial manures do add to the fertility of the soil.

The variety of Potato under trial was a selected form of Myatt's—perhaps the best garden Potato in cultivation when well grown. The sets were all strongly sprouted before planting. They were set out in rows 2 feet apart and 1 foot from set to set in the row. Planting was done on April 3rd with the ground in splendid condition. All the manures were strewn along the rows and mixed with the soil before the sets were planted. The ground was hoed during summer with a Dutch hoe twice, and the crop lifted in the beginning of August. The difference in the weight of crop arose from the size of the tubers in the several plots, all tubers under table size being discarded. In some cases there were never more than four table size tubers at a root, in others not fewer than ten, and these of a larger size. I give the results in tabular form, and may explain that 20 represents the smallest crop, 30 the largest, the intermediate giving the proportion of the others. The cost is given as approximating to what they would cost gardeners taking small quantities. The dressings were perhaps heavier than was quite necessary. It may also be added that although the very inexpensive combination of kainit and nitrate of soda gave very excellent returns, the next crop will most likely suffer after that manure. It is necessary to state that for Potatoes sulphate of ammonia is a much better material from which to derive ammonia than nitrate of soda, the latter passing very rapidly from the soil, while the former is slower in action and of a more lasting character.* It also seems to act better in combination with other manurial agents. Though higher in price it must be remembered that the ammonia derivable from a first-class sample of sulphate of ammonia is as 5 to 4 of nitrate of soda. The heaviest crop (30) represents about thirteen tons per acre.

Name of Manure.	Quantity per Acre	Cost per Acre in small quantity.	Comparative Crop.
None			20
Chloride of potash	2½ cwt.	25s.	20
Kainit	2½ cwt.	12s.	22
Superphosphate of lime	3½ cwt.	21s.	20

HISTORICAL JOTTINGS ON VEGETABLES.

SMALL SALADS.

CONCERNING tastes, as a familiar saying informs us, disputes are vain, and are reasonably judged to be so, for in the matter of the palate no one has any right to quarrel with his neighbour's likes or dislikes, and it would be of no use to attempt to change these by force of argument. One exception to the general rule, however, lies in the case we sometimes meet with, where an individual professes to dislike some article or compound which he has never tasted. We have reason on our side if we ask him to give it a fair trial. Much, no doubt, depends upon early training in this as in other things; and there are plenty of instances where generations have persistently eaten of a dish which later generations have as uniformly rejected, not because of its unwholesomeness or scarcity, but because its place was occupied by some new dish, which has had its turn of popularity. Were the salads of three or four centuries ago to be concocted

now we question if they would be partaken of by modern Englishmen; even supposing they were presented apart from their history, both appearance and flavour would probably tell against them. "Salad," say the dictionary makers, comes from a French word spelt almost similarly. Our forefathers, indeed, seem to have frequently written it "sallet." The origin is presumed to be the Latin *sal*, because the compound thus styled contained a predominance of salt. I cannot regard the derivation as quite satisfactory, but am unprepared with a better. Such salads until about the commencement of the Georgian era, contained none of those plants we now commonly employ, but such as could be gathered by fields or waysides, made pungent by the Onion and its allies, or perhaps in winter by the addition of spices and pepper. Being not unusually mixed in bowls of metal, there must have been at times an unwholesomeness about the salad whenever acids in any quantity formed part of the compound. The stronger acids, such as vinegar, were occasionally displaced by the leaves of one of the Sorrels, which would suffice to give a mild acid flavour. Amongst the plants that have been specified as favourites in old salads we find the Lamb's Lettuce (*Fedia olitoria*), the Burnet (*Poterium Sanguisorba*), the powerful and abundant Hedge Garlic (*Erysimum Alliaria*), that presumed strengthener of the heart the Cuckoo Flower (*Cardamine pratensis*), with others doubtless of the Cruciferous or Cress tribe allied to our garden species.

This Cress, the *Lepidium sativum* of botanists, though now so familiarly associated with the Mustard, was not eaten green with it until a comparatively recent date. The seeds of the Mustard species have a long history, but we do not know the name of the man who first ate or suggested the eating of the young plant in a green state. Lists of the street cries of old London do not tell us of any early vendors of vegetables who carried round Mustard and Cress; indeed to the present hour this small salad is not often sold by the street costermongers, though raised all the year through for the market, the demand for it varying considerably. It is likely the two became thus associated about the beginning of the reign of George III. It would appear, however, from remarks in sundry old books on gardening that for some time the young leaves of the Turnip were eaten with Cress to impart some pungency.

Concerning the general history of the cultivated species of Mustard, we may first note that some kind, hardly to be identified now with certainty, but which may have been our *Sinapis nigra*, was grown both in Europe and Asia centuries before the Christian era, and where circumstances proved favourable it attained to a size which would justify the comparison in Matt. xiii. 31. By the Greeks and Romans Mustard seems to have been valued both as a medicine and as an article of diet, and probably it was brought into Britain during the period of Roman rule. Its effect upon the eyes is supposed to have originated the Latin name from *sino* and *opsis*; others connect it with the Keltic *neup*. Mustard, the English name, comes of course from the French *moutarde*, though the old appellation for it is said to have been *senevé*. A household book containing records of the expenditure of the Duke of Northumberland in some years of the sixteenth century acquaints us with the fact that his retainers disposed of about 160 gallons of the seed per annum: it was eaten whole boiled accompanied with vinegar. The cultivation of the Black Mustard in fields is mentioned before that date; and Tusser, writing upon the "Five Hundred Points of Good Husbandry," directs that the seed be sown in February after rain.

The White Mustard (*Sinapis alba*) was introduced during the reign of Elizabeth, and Gerard informs us that he helped on its diffusion through Britain by distributing packets of seed wherever he found persons willing to grow the plant. It is a species that grows apparently wild in South Europe and Western Asia. His comments upon Mustard imply that it had begun then to be used as a condiment in the mode we place it on our tables, but the seeds were ground very coarsely. A doctor who was one of Gerard's contemporaries, recommends Mustard as a strengthener of the voice if the powdered seeds mixed with honey into a paste are taken early in the morning, which might furnish a hint to modern speakers and singers. For a good while much Mustard seed was sent to the metropolis from distant places, which were supposed to produce better crops than did the soil near London, though this was really but a fancy. Thus Coles, about the date of the Restoration, mentions Tewkesbury as a town that grew a good deal of Mustard in its vicinity, and which was sent long distances by the slow conveyances of the age. Durham, too, amongst other places became famous for its Mustard, not only for the reason above, but because the first "flour of Mustard" was manufactured there in 1720, the inventor of the process being a Mrs. Clements. George I. accepted samples of the article, the nobility and gentry patronised it, and so

* I have tried experiments with saltpetre (nitrate of potash), but the results have been rather disappointing. Its cost is high, about 50s. per cwt.

Durham Mustard obtained a name it has kept to this day. When Mustard, the white more particularly, began to be appreciated by farmers the seeds were largely sown in the fenny districts of Cambridgeshire and Lincolnshire. Essex and Kent are also counties where Mustard fields frequently greet the eye.

The Garden Cress (*Lepidium sativum*) is a native of Greece, a fact only verified at a comparatively recent date. But it was well known before then that the Greeks in early times grew the plant freely, believing it answered the double purpose of food and medicine. Xenophon is reported to have advised the Asiatics to cultivate it, because it would help them to overcome the languor caused by an eastern climate. If the name "cress" or "kers" is found, as some say, in most primitive European languages we should conclude it was grown, or at least gathered, throughout Europe many centuries ago. Pliny believed that even insanity could be cured by an abundance of Cress; and Cogan, soon after it had attained to popularity in England, advised persons to eat it who wished to have their wits sharpened! For, however common it may have been in gardens on the Continent, Gerard assures us it was hardly known here until the middle of the sixteenth century, the seed coming from France. From the copious directions contained in books of instruction in gardening compiled last century as to how best to cultivate Mustard and Cress, it is evident this small salad was much in demand and freely grown in the open air, as also in frames, to supply the market from autumn to spring.

The spring, again, has been considered to be the season when the Watercress should be eaten as a purifier of the blood, and in the olden time children were physicked with a drink made by boiling its tops with those of the Scurvy Grass (*Cochlearia officinalis*) in spring water. According to Mr. Glasspoole, it was not until 1808 that this plant (*Nasturtium officinale*) was grown in beds as it is now, yet the street girls had cried bunches of the vegetable at least a hundred years before that date. They obtained them (or others did) from the rivulets and ditches of the suburbs. We read of their being picked about Tothill Fields, and the actual banks of the Thames west of London. Hackney also produced its wild Watercresses, and they are still cultivated in that neighbourhood. At a little nursery garden in the Wandsworth Road, near Vauxhall, called Springfield, there was a Watercress ground a few years ago, where once the plant may have grown wild. The celebrated gardens at Springhead near Gravesend were formed about seventy years ago by a Mr. Bradbery, who afterwards had several acres of land planted with Watercresses near Rickmansworth. Another memorable Watercress ground is also in Hertfordshire, near the Rye House, the scene of a memorable intended plot, and beside the Lea and the New River; while Watercresses are extensively grown near Croydon, and supported by the sewage of that town, but the method is not considered by all persons unobjectionable.—J. R. S. C.

ROYAL METEOROLOGICAL SOCIETY.

THE usual monthly meeting of this Society was held on Wednesday evening, the 20th ult., Mr. R. H. Scott, M.A., F.R.S., President, in the chair. T. G. Benn, Capt. C. F. Cooke, Francis Galton, M.A., F.R.S., Prof. S. A. Hill, B.Sc., Capt. A. W. Jeffery, G. Paul, F.G.S., F.R.H.S., R. Vevers, H. T. Wakelam, and E. Wells were balloted for and elected Fellows of the Society. The following papers were read:—

(1.) "The Great Storm of January 26th, 1884," by William Marriott, F.R.Met.Soc. This storm was remarkable for its violence and large area, as well as for the unprecedentedly low barometer reading at its centre. The author has prepared isobaric charts for each hour from noon on the 26th to 3 A.M. on the 27th, and by this means has tracked the storm across the British Isles. The centre of the depression appears to have first reached the north-west coast of Ireland at noon, and passed in a north-easterly direction over the north of Ireland and across the middle of Scotland, reaching Aberdeen about midnight. Its rate of progress was therefore about 30 miles an hour. A violent gale was experienced all over the British Isles, the greatest hourly velocity of the wind being 68 miles at Valencia at 11 A.M., 70 miles at Holyhead at 2 P.M., 63 miles at Falmouth at 3 P.M., 69 miles at Armagh, and 59 miles at Aberdeen at 5 P.M., 58 miles at Greenwich from 5 to 7 P.M., and 76 miles at Alnwick at midnight. Thunderstorms occurred on the south-eastern side of the depression, and travelled across the south of Ireland and England at the rate of about 30 miles an hour. The lowest readings of the barometer (reduced to sea level) yet reported were 27.32 ins. at Kilcreggan at 8.30 P.M., and 27.32 ins. at Ochertyre, near Crieff, at 9.45 P.M. In the southern part of England, directly after the minimum had occurred, there was a very sudden rise in the reading of the barometer, in some cases amounting to 0.08 inch in five minutes. From an examination of previous records it appears that there has never before been so low a barometer reading as 27.32 ins., so that this storm may be considered as one of the most remarkable that has occurred in the British Islands.

(2.) "The Height of the Neutral Plane of Pressure and Depth of Monsoon Currents in India," by Prof. E. D. Archibald, M.A., F.R.Met.Soc.

(3.) "The Sunrises and Sunsets of November and December, 1883, and January, 1884," by Hon. F. A. Rollo Russell, M.A., F.R.Met.Soc. The author gives a very interesting account of all the special features of the remarkable sunrises and sunsets which have been observed from November 8th

to February 2nd. The following are stated to be the marks distinguishing the peculiar sky-haze from cirrus:—

- 1, It is commonly much more evenly spread over the sky than cirrus
- 2, It is visible (except when very dense or in the neighbourhood of the sun) only about time of sunrise and sunset. During the day not the faintest trace obscures the clear azure, whereas cirrus becomes more distinct with more daylight.
- 3, When actually glowing with bright colour it loses its wavy appearance.
- 4, It has no perceptible motion, unless perhaps when watched through a long period.
- 5, It does not interfere with the clear definition of the moon or brilliancy of the stars.
- 6, It lies almost without exception in long streaks, stretching from between south-south-west and west-south-west to between north-north-east and east-north-east.
- 7, Its radiant point lies not on the horizon, but far below it.
- 8, If both cirrus and sky-haze be present, the sky-haze begins to shine with a red light soon after the cirrus has ceased to glow above the western horizon. When cirrus is present, however, there is in general a reaction of effects.
- 9, The sky-haze is destitute of the fibrous twists and angular branches of cirrus, and, since the sunlight leaves it in regular progression, it must be stratified at the same uniform level.
- 10, It has always been visible on every clear day for more than two months, and has been quite independent of wind and weather.

SOIL FOR NEPENTHES—A DEPARTURE.

"WHAT everybody recommends must be right" is an axiom not to be lightly disregarded; but it may be well to remember that everybody recommended peat for Ferns once, but now the most healthy and vigorous are grown in loam. Everybody also not long ago recommended porous pots for all kinds of plants, whereas it is now found they will flourish equally well, if not better, in pots that are glazed. Everybody now appears to recommend a rough, porous, almost soil-less compost for Nepenthes; even Mr. Abbey's advice is given on the follow-my-leader principle. No doubt good plants have been grown and are now produced in the fluffy medium recommended on page 163; but will they not grow better, hardier, sturdier, healthier, and produce more, finer, and better-coloured pitchers when grown in a more substantial medium?

Not many years ago one of the most healthy stocks of Nepenthes ever seen produced in the same limited time was raised and grown by Mr. Bause in the Melbourne Nursery, Anerley, for Mr. Wills. The plants were not of the largest, but for texture and colour of foliage, with proliferousness of pitchers, they equalled the best of their age and excelled most. In his experiments in growing Pitcher Plants the cultivator found that he could depart from the orthodox compost with advantage, and just as he receded from the fluff and treated the plants to a "bit of loam" so did their strength increase. This led him to adopt the same compost as he employed for Dracenas, or what most persons would consider excellent for Fuchsias. So satisfactory was the experiment that practically the whole of the plants, and there were several hundreds in 5 and 6-inch pots, were potted as if they required something more than air and water to feed on. The newer and more expensive kinds were without hesitation potted in the manner indicated, the pots of the size mentioned not containing more than 2 inches of drainage—in fact, not so much. They rooted in the soil with the greatest freedom, the fibres multiplying and coiling round the pots just as freely as those of a Pelargonium. There is no mistake about this, for I turned out many of the plants and examined them carefully. In every case those were in better condition that were growing in good soil than the few others that were left in the orthodox medium; indeed, if this had not been so, nothing is more certain than that the new practice would have been abandoned.

Although I am unable to state with exactitude the compost employed for the plants, yet it will be near enough for practical purposes to describe it as consisting of from one-half to two-thirds of sound turfy loam, the remaining portion of peat and leaf soil, with a liberal addition of sand and a 7-inch potful of horn shavings to a bushel of soil. When the compost was used it was pressed down with the same degree of firmness as in potting Dracenas.

If any error has been made in describing the method of culture, Mr. Bause, who is now established in the Portland Nurseries, South Norwood, will be able to correct it; also to indicate, if needed, any varieties that are not so amenable as others to the treatment in question.—EXPERIENTIA DOCET.

A NEW GARDEN.

THE KITCHEN GARDEN.

Enclosures.—Boarded fences, glass, stone, and brick walls have all been tried for enclosing kitchen gardens, the use of either material, except bricks, being more frequently influenced by certain local circumstances than from any decided superiority. For example, at Crowborough Cross on the forest ridge in Mid-Sussex there are extensive beds of thin sandstone so easily excavated and prepared for building as to cost less than any other material, and as this stone is

hardly so thick as an ordinary building brick it makes excellent garden walls. But I have seen walls of large square blocks of limestone so hard as to be very expensive both to excavate and dress that were a decided mistake. Glass walls in the form of narrow fruit houses are undoubtedly the best enclosures in cold bleak situations, insuring as

they do an abundant and regular supply of Grapes, Peaches, Nectarines, Apricots, Figs, Plums, Apples, and Pears. Unfortunately such enclosures are not only costly to build, but they involve a heavy subsequent expenditure for skilled labour to cultivate the trees. It should not, however, be forgotten that the culture of fruit in such houses is decidedly profitable, soon covering the expense of building as well as of cultivation. Growers of fruit for market may therefore certainly adopt this method with advantage, but it is only in exceptional cases that glass walls are likely to be built in private gardens. Wooden fences can hardly be recommended as permanent enclosures, but they continue sound for many years if due care be given to dressing the parts below the surface, and to painting the remainder. A useful form of this fencing was figured and described in full detail in the *Journal* in 1876, and it was republished in the "*Gardener's Year Book*" for 1877.

Brick walls are undoubtedly best for gardens generally, and bricks are more frequently used than any other material for this purpose. "In selecting bricks," says the "*Gardener's Year Book*," "clap them together—if they ring well, and when broken show that they are burnt through, they will answer the purpose. A hard clamp-burnt grey stock is all that is wanted for strength; for foundations use clinker-burnt marl stocks." Experience in building proves the importance of this advice, for without close supervision some soft bricks are certain to be used, to the subsequent disfigurement of the wall, as

Fig. 39.

they will crumble after exposure to a sharp frost or two. I may add that the hints on building in the "*Year Book*" are thoroughly practical, and I have repeatedly found them afford information not to be

found in such books as Dodson's "*Art of Building*," and Allen's "*Building Manual*." For appearance, well-burnt red kiln bricks are decidedly preferable to clamp bricks, but they are more expensive, costing 35s. a thousand, as against 25s. a thousand for clamp bricks. Where rigid economy is not insisted upon, not only should kiln bricks be used, but the wall should be rendered as ornamental as possible.

The garden wall at Old-

Fig. 40

lands is a remarkable example of good taste, and is a decided step out of the ordinary method. It was designed by the late Sir Digby Wyatt, and is of solid 14-inch brickwork, 9 feet 6 inches high from ground line to coping, and the coping is cleverly contrived with three of Gubb's coping bricks; A. fig. 39, imparting due importance and finish to the wall. Buttresses are built outside the wall as at B (fig. 39), where I have given full details of the brickwork to show how it is managed so as to have the ends of the bricks perfect outside the slope. A ground plan of a buttress is given in fig. 40, and the outer lines are added to show the width of the footings.

The small doors of this garden, designed by the same eminent architect, are so superior to ordinary garden doors that I have shown the construction and method of hanging of one of them fully in figs.

Fig. 41.

41, 42, and 43. They have been in constant use for upwards of thirteen years, and are practically as perfect as when first put up. This utility and durability is owing to the hanging, the bracing, and hinges, and to the absence of door frames. The hooks of the hinges are strongly bedded in stone blocks E (fig. 43), the lock and latch also fasten in a stone block D (fig. 42), which is inside the garden, where the doors shut against the wall in a rebate, F (fig. 43) made in the brickwork, so that the use of frames is avoided—a simple but important matter when it is remembered how prone timber is to shrink and swell when exposed to rain and sunshine. Fig. 41 shows the outer side neat and serviceable and also unclimbable, a by no means unimportant matter in a garden door.

The buttresses have been turned to account for the culture of Tea Roses, a different sort being trained around each buttress, the various aspects retarding or hastening the expansion of the flowers, and thus affording a valuable succession of bloom. Taken apart from this particular wall the transverse section A (fig. 39) is given as a useful

example of a strong garden wall, suitable for any position and perfectly safe under any exposure.—EDWARD LUCKHURST.

(To be continued.)

ROSES NIPHETOS AND SAFRANO.

BEING under the impression that Niphetos was one of the most valuable Tea Roses grown I was greatly surprised at Mr. Bardney's abuse of it (page 104). We find it free-blooming and as strongly scented as any, and being white it is of more value than any other variety, unless we except Maréchal Niel. One good bloom of Niphetos is worth four

Fig. 42.

Safrano buds. To prove this I send blooms of Niphetos, Catherine Mermet, and Safrano, the former at the present time being, as you will find, as sweetly scented as any of them.—W. IGGULDEN.

[The blooms of Niphetos are quite as sweet as the others and much finer, but we cannot regard any of them as particularly fragrant. There

Fig. 43.

are more blooms of Niphetos sold in London at the present time than of any other Rose.]

ECHEVERIA RETUSA.

THIS useful free-flowering winter plant is of easy culture, and propagates freely from offsets taken with an inch or two of heel

when the plants have flowered, and inserted singly in 60-size pots filled to the rim with an admixture of nearly three parts light loam and one of leaf mould, with a dash of sand. They will root freely if then placed on the staging over the front pipes in a vinery and damped overhead two or three times a day with the syringe when the house is being damped, which, the plants being succulent, will be sufficient to keep them fresh until they have emitted roots, when they should have water in the usual way when necessary. When the plants have partly filled the cutting pots with roots they should be shifted into 48's and stood on sifted coal ashes in a frame in a warm aspect, and kept close for a few days, being syringed on bright afternoons, until the plants have made fresh growths, after which the frame should be ventilated freely on all favourable occasions, and sashes tilted a little at night. About the middle of July remove them altogether, which will not only afford the plants head room but also cause them to make a sturdy growth; moreover, the plants as they increase in size should have more room given them in the frame. Upon the approach of frost they should be removed to a pit or house where they could have plenty of light and air and a minimum temperature of 40° or 45°, which, with a rise of 10° or 15° during the day, would enable them to commence flowering about Christmas, and continue in flower for three or four months onwards. The plants, however, may be had in flower if necessary five or six months by introducing a small batch into the forcing house in October and at short intervals till Christmas.

From the time the plants commence throwing up their flower spikes they should have liberal supplies of weak liquid manure three or four times a week to the roots. The Echeveria under this notice is a valuable house and conservatory decorative plant, as it is also to cut from, inasmuch as the flowers, which are of a deep orange colour, Hyacinth-like in shape, and borne on trusses on the top of the spikes, owing to the nature and substance of the footstalks, keep fresh in water for several days after being cut. Specimens from 15 to 20 inches high and nearly a foot through, and which have been grown in the manner indicated in this paper, are at the present time round the edges of the staging in the conservatory very effective intermixed with Primulas, Cinerarias, Hyacinths, Cyclamens, and Ferns.—H. W. WARD.

HARDY FRUIT GARDEN.

Grafting.—Many sorts of Pears so often prove worthless owing to some defect of soil or climate that the planting of a given list of sorts that answer well in another locality frequently causes much vexatious loss of time. The stations are prepared, the trees planted, trained, pruned, and brought into condition for bearing fruit, which after all is unfit for anything but stewing. In all such instances do not destroy the trees, but re-graft them with some sort that has answered well in your garden. This may be done as soon as the sap is in motion, with wood of last year's growth that has been kept plump and fresh for the purpose by being thrust into soil on the north side of a building or wall so as to keep the buds dormant as was advised a month ago. This grafting is to be done upon the branches and not on the stems, each branch being shortened to a foot or less from its base according to its position. For example, the lower branches of a pyramid should be left twice as long as those near the top; but the branches of a standard or bush are reduced to an uniform length. One scion is inserted into each branch either by cleft or whip grafting, the first being preferable for large, and the last for small branches. Any favourite method may be followed if only due care is taken to make the inner bark of the scion and stock meet, to bind them together securely, and to exclude air from the point of union by covering it with grafting wax or prepared clay. By thus grafting upon the branches a tree is brought into full bearing in half the time required for the development of a new stem and branches. Old trees in a state of barrenness, with stem and branch intact, and with thick, soft, healthy bark, become wonderfully fruitful if the branches are shortened moderately and a graft inserted in each of them. The best guide in shortening the branches is to remember that the growth of the scion is required solely for the production of fruit, and therefore it must be kept well out in sunlight and air away from the interior of the tree, which forms an admirable support and foundation for it. There are few more pleasing sights in fruit culture than old trees so rejuvenated. We have had such complete success with the plan in our own practice that we heartily commend it to the notice of our readers. Grafting young nursery stock is so clearly a matter apart from the duties of a private garden that it is unnecessary to explain the process here.

FRUIT-FORCING.

PEACHES AND NECTARINES.—*Earliest House.*—The fruit having set

thickly will need thinning before disbudding can be brought to a close; and as the main principle in Peach-forcing is to carry on every operation without causing a check, a few of the least promising fruit should be removed daily as disbudding is performed, and at the same time pinch back many of the growths that are retained to attract the sap to the fruit, and which are afterwards removed, for although Peaches fruit freely on spurs formed early in the season, they never produce such fine fruits as are obtained from clean short-jointed growths a foot or more in length. With the increased sun power, and as cold cutting winds may be expected, sharp currents and sudden changes of temperature must be guarded against by ventilating early and gradually, and reducing it in the same way, rapid fluctuations being highly injurious. Until the stoning is past it will be advisable to continue the low night temperature previously advised, or 60° in mild weather, and 5° less in severe weather, with an advance of 10° to 15° by day in sunny weather, but when dull 65° should be the maximum until the stoning is completed. Syringe the trees twice on fine days, but be more sparing of water when dull, always syringing early in the afternoon, so as to get the leaves dry before night. When it is not advisable to syringe the trees counteract the drying influence of fire heat by damping the floors and borders, and sprinkle the floors before nightfall with tepid liquid manure.

Succession Houses.—Disbudding must be attended to, also thinning the fruits where too thickly set. In later houses observe a medium course with regard to moisture until the fruits are set and swelling, when the directions given for the management of the early house will apply. Inside borders must not be allowed to become dry, as many crops of Peaches have been injured or lost through being kept too dry when in active growth.

MELONS.—Due attention must be given to stopping, thinning, and tying the young shoots as they advance, also in impregnating the blossoms on fine days when the pollen is dry, as it does not do to leave this important matter to chance or insect agency. When the flowers are set stop the shoots one joint beyond the fruits, and when these are swelling they should be thinned, leaving about four on each plant, or less, according to the vigour of the plants and the size the fruits are wished to attain, having them as evenly distributed as possible. When the fruits are swelling it will be necessary to earth-up the roots, applying the soil firmly, and having it the same temperature as the bed. Give a good watering previously to earthing-up the roots with tepid liquid manure in a weak state. The bottom heat should be kept steady at 80° to 85°. Admit a little air at 75°, but not so as to lower the temperature. Increase the ventilation with the sun heat, keeping the temperature at 80° to 85° through the day, and close at 85°, then syringing moderately, and allow an advance to 90°. Keep the temperature at 70° to 75° in the daytime when the weather is cold or the sun obscured by clouds, and 70° at night, falling to 65° in the morning. Omit syringing the plants in dull weather, but maintain a genial condition of the atmosphere by damping surfaces in the morning and afternoon, keeping the evaporation troughs filled with liquid manure. Successional sowings and plantings will need to be made according to the requirements of the establishment. Plants in dung-heated frames will need a little earth added to the sides of the hillocks or ridges as the roots protrude, but water will not be much needed, as the moisture from the fermenting materials will be sufficient in most cases, and when needed it must be given in a tepid state, avoiding wetting the foliage and collar of the plants. Keep the collar free from lateral growth, and remove every alternate lateral on the principal growths when they are quite young, reserving only four shoots to each plant, training two to the back and the other two to the front of the frame or pit, and stopping when about a foot from the sides. See that the linings are regularly attended to, employing good night coverings on the lights. Ventilate carefully, but lose no opportunity of doing so, and close early in the afternoon.

CUCUMBERS.—Afford plants in bearing liberal supplies of tepid liquid manure, syringing moderately in the morning and at closing time in bright weather, but rest satisfied with sprinkling the paths and beds twice a day in dull weather, so as to counteract the drying influences of fire heat, and maintain a growing atmosphere, keeping the evaporation troughs filled with liquid manure, or, failing those, sprinkle the floors before nightfall with liquid manure. Careful and regular attention must be given to tying and removing superfluous shoots or fruits, the greatest evil in Cucumber-growing being overcrowding and overcropping.

Young plants are now making vigorous growth and need training regularly and not too closely over the trellis. Stop the shoots when they have extended over about two-thirds of the trellis, and the laterals or side shoots showing fruit may be stopped a joint or two beyond the fruit. Remove all superfluous fruits and most of the male blossoms. Water must be given as needed in a tepid state, and a little soil previously warmed added to the sides of the ridges or hillocks from time to time as the roots protrude until the space is filled. The linings of dung-heated frames or pits must be well attended to, keeping up a reserve of fermenting materials for making new beds.

PLANT HOUSES.

Stephanotis floribunda.—Plants that have up to the present time been kept cooler and in a drier atmosphere than the stove will, if introduced into brisk moist heat, soon commence growth. If potting is needed, this may be done as soon as the roots commence advancing, employing a compost of good peat and loam in equal proportions, to which is added a little bonemeal and broken charcoal. Do not disturb the old ball more than is necessary in removing the drainage from amongst roots and loose soil from

the surface. The pots in which they are to be grown should be liberally drained and the soil pressed in firmly. After potting, supply water carefully until the roots are growing freely. If potting is not needed, top-dress with some rich compost, and feed the plant liberally when in active growth. If the plant is trained upon a trellis elevate it close to the glass, and as the new growths extend secure them to small cords. If any young plants are needed take off the growths with a heel when about 3 inches in length, and insert singly in small pots in sandy peat; give a good watering after insertion, and place them in a close frame or under a bellglass.

Clerodendron Balfourianum.—The earliest plant that was started will now have young growths that are in the best condition for striking. The portions selected should be about 3 inches in length, and taken off with a sharp knife close to where they join the old wood. Insert two cuttings, one on each side, of 2 or 3-inch pots, and, after watering them, place them in a close frame, and nearly every one will form roots. These when ready should be placed into 6 or 7-inch pots and grown on in any warm house, and before the close of the season will have well-ripened shoots several yards long. The shoots the following season may be trained round four or five stakes and forced into bloom for the side stages of the stove, or retarded for flowering in the conservatory during early summer. Young plants produced by this method are invaluable for forcing.

Bougainvillea glabra.—Young shoots taken off and treated as advised for the *Clerodendrons* will soon root, only these should be inserted singly. If grown and potted on until they are placed in 8-inch pots, they will be found useful for flowering in the stove another year, or in the conservatory during the summer. By preparing plants of this description for cool structures that have to be kept gay during summer an attractiveness is produced which cannot be obtained by the ordinary summer-blooming plants. During summer there is too much sameness in conservatories and other similar structures, which can only be broken by the preparation of such stove plants that will flower and flourish for some time without injury. The labour in the production of these quick-growing plants is little. Small plants of *Allamanda Wardleyana* (Hendersonii) may be prepared and grown on for the same purpose.

Ixoras.—These plants may now be repotted if they need it, and will do well in either peat or loam, or both combined; the former with a good dash of coarse sand is the best, as peat does not become sour if good through constant watering the same as loam. The plants to be potted now should have been pruned back some time ago, and have commenced growth. If this is not done no time should be lost, and the operation of potting postponed for a time until they have commenced growth. In potting the roots should be disturbed as little as possible, and the new soil should be pressed firmly into the pots. After potting water must be applied with great care until the roots are growing freely. If practicable, plunge the pots in a bottom heat of 80° to 85°, and the top heat at night from 65° to 70°. Syringe the plants twice during fine days. If specimen plants are wanted tie out the shoots as growth extends, bringing the strongest well down to furnish the base.

Young stock may be raised by inserting the tops of the shoots that are pruned back; these should be inserted singly in 2-inch pots containing sandy soil, and placed in a close frame until rooted. These young plants can be grown on without being stopped, and are invaluable, with one large truss upon them, for purposes of decoration. If plants with from four to six shoots are required, the young plants must be pinched until the requisite number are formed, and then allowed to grow without stopping until they flower.

Seeds of *Primulas*, *Gloxinias*, *Begonias*, *Cinerarias*, *Cockscombs*, and *Celosias* may now be sown. The three first mentioned should be sown upon the surface of the soil in the pots or pans employed. The surface soil for the former should be light, and composed principally of leaf mould that has been passed through a fine sieve. For the second and third a sandy surface is preferable. The seeds of the others may be lightly covered with any fine open soil. Water with a fine rose after sowing and cover with a square of glass, and keep the pots or pans shaded from the sun until the seeds germinate. Care must be taken after the seed is once sown that the surface soil never approaches dryness, or the seeds may fail to germinate freely. After sowing stand or plunge the pots or pans in a heated structure.

THE FLOWER GARDEN AND PLEASURE GROUND.

Formation of Hedges.—It is not yet too late to form new hedges or repair old ones. The common Yew and Hollies are both well adapted for the purpose, but the latter should not be planted till the end of this month. Procure strong plants, and let the positions for them be well drained, manured, and deeply dug. If each plant touches those next it a good hedge will soon be formed, as there is no necessity to cut them back. During the first year they must not be allowed to get dry at the roots, and, as a partial preventive, mulch early either with strawy manure or grass from the mowing machine. For surrounding extensive grounds and plantations a good hedge may be formed either with a mixture of Privet and Quick Thorn, or where the positions are not very wet, with Beech and Quick Thorn. These, too, ought to have well-prepared positions, and may be planted in double lines about 12 inches asunder, and the plants the same distance apart and angled. Cut them down to within 6 inches of the ground, shortening them the second season to within 12 inches of where last shortened, and again the next spring in a similar manner, the object being to secure good bottoms, without which a hedge is of little service. All young hedgerows should be well protected, have the ground annually lightly dug on each side of them, and be kept clean.

Pruning and Cutting Down Shrubs.—When trimming the fronts of shrubberies and other prominent positions use only the knife or secateurs, as, if other tools are used, the leaves are almost certain to be much disfigured. Nearly all the shrubs and evergreens are improved by occasional prunings, both in order to restrict those overgrowing their neighbours, and also to improve the form of various specimens. Conifers, where growing irregularly, may be freely pruned, and if there are two or more leaders or central growths the best should be preserved and the others cut away. If in any case the leader is damaged, select a good branch, and stake this upright in the centre of the trees, and it will soon take the lead. Any evergreens, such as common Laurels, Portugal Laurels, Hollies, Yews, Sweet Bays, Laurustinus and Box, as well as flowering shrubs that have either grown too tall or have naked stems, may safely be improved by being cut down to near the ground, as when thus treated they seldom fail to break freely and strongly. A saw is the best for this work, and the wounds should be rounded off with a knife to facilitate healing; jagged wounds, on the contrary, holding water, which encourages decay. The mere fact of cutting down sickly evergreens and shrubs, however, will not renovate them, as these in most cases require lifting, the roots being lightly shortened and replanted in good fresh soil. On clayey soils plant rather above the level, and such soils will be much improved if surface or open drains are cut, and good outlets provided.

Lawns.—These are much benefited by occasional rollings at this time of the year, this fixing the grasses prior to their forming entirely fresh roots, besides firming the ground, also removing inequalities when these are not very large. Dry days are best for this work, and prior to rolling the wormeasts should be distributed with brooms as much as possible, but do not collect them, as they serve to keep the ground from being exhausted. Lawns seldom get a dressing of manure of any kind, but they need it in a great many instances (this encouraging the grasses and keeping down moss and Daisies) soot, lime, and wood ashes mixed with six times their bulk of fine loam or garden soil. Applied liberally and well worked in with iron rakes or bush harrows, will serve the double purpose of destroying the moss and improving the sward. Where the grass is thin, sow seeds as mixed and supplied by the vendors. Badly drained lawns are quickly improved by cutting a few drains, and it is not yet too late to do this.

Roses.—Any that have been laid in during the winter ought to be planted as soon as the state of the ground permits. If they are to go where Roses have been growing previously, a liberal quantity of fresh loamy soil ought to be given them. Dwarfs on the Manetti stock must be planted deeply, so as to bring the point of union with the graft or bud below the soil. Standards should be staked up at once. They may be pruned at once, and in warm dry localities many of the established may also be pruned, but in low-lying positions, where late frosts are experienced, it should be deferred another fortnight.

Herbaceous Borders.—Many plants in these, notably the Phloxes, Asters, and Japanese Anemones, if not lifted and divided in the autumn, should now be attended to, otherwise they become too much crowded. They are also gross feeders, and lifting admits of thoroughly enriching the borders. Better have a few strong crowns or shoots than many weakly ones; therefore freely thin out all not divided and at all crowded, and fork into the borders a liberal dressing of either well-decayed manure or good leaf soil.

THE BEE-KEEPER.

ABOUT LIGURIAN BEES.

I AM glad to notice that a spirit of inquiry is at last being aroused concerning the merits or demerits of foreign bees, and the wisdom or unwisdom of introducing them into our apiaries with the object of improving (?) the strain or breed of bees in the United Kingdom. I have long ago formed a very decided opinion on the question, but felt some diffidence in hastily expressing it, because of the almost unanimity with which modern writers on bees have sounded the praises of Ligurians. It is becoming quite certain that sooner or later the truth must be told, and so I venture to give publicity to some facts which bee-dealers as well as bee-keepers will do well to consider if they value their own interests.

No writer that I know of has emphatically condemned these bees except Mr. Pettigrew, and his opinion lost the weight it would otherwise have possessed for two reasons—first, he had no personal experience of Ligurians; and second, because he wrote just as strongly against bar-frame hives, declaring they possessed no merit to recommend them in preference to skeps. We cannot, therefore, wonder at bee-keepers taking a great deal for granted when all the high authorities were in favour of the new race of bees, and the bee journals were full of advertisements of pure Ligurian queens, with marvellous accounts of their superiority over the common black bees. Nor should we omit to mention the fictitious value which high prices gave them in the eyes of those who think that nothing can possibly be good which is not dear.

I feel quite certain that we should ere now have seen the last of Ligurian bees, so far as making a profitable business out of their sale, but for the curious fact that almost everyone is delighted with them

on a first acquaintance. The novelty is pleasing, the care required in introducing a new queen lends a charm to the operation, and, when success is assured, the pleasurable anxiety with which the first young Ligurians are watched for adds to the interest taken in the little strangers. Then comes the extraordinary fecundity of many Italian queens, the immensely strong stocks and numerous swarms which are the natural outcome of this, and finally their extreme docility. This is their greatest recommendation. The delighted bee-keeper can handle his new bees so easily, rarely receiving a sting, he becomes quite an expert, and says so much in their favour that he is afterwards very unwilling to acknowledge his mistake, and takes much convincing that all is not quite so certain as he supposed. And so he makes excuses for his want of success with his new hobby—"the season is unfavourable;" "they will do better next year," and so on. As time passes, the truth begins to dawn upon him. He never had robbing to such an extent before; his surplus honey is not worth harvesting; he buys sugar in autumn by the hundredweight—probably a touch of foul brood startles him; his bees are much more troublesome than they used to be; and after a few years' experience with Ligurian bees he is a wiser and poorer man, and ends by either giving up bee-keeping altogether, or becomes so thoroughly dissatisfied with Ligurian bees that the very name is odious to him.

This is not an overdrawn picture. I assert that it is the experience of 80 per. cent. of those who have tried the experiment of ligurianising an apiary. It would occupy too much of your space were I to go through my own experience in detail, so let me say very briefly I was often asked in years gone by why I did not "go in" for Ligurians. I thought my objection a sound one. It was this. I had not the least prejudice against them, but I had always found my black bees so satisfactory I did not care to make a costly and troublesome experiment without being quite sure of an adequate return. However, circumstances occurred one autumn a few years ago which induced me to give Ligurians a trial. I procured some half-dozen queens from different dealers and successfully united five of them to as many good black stocks. The result of my experiment was very much as described above, except that I should have to colour the picture a little more strongly to faithfully reproduce what I suffered. Eventually I got rid of Ligurians, and at the present moment if I were offered the chance of having my apiary ligurianised free of cost with the best strain extant, and a bonus of £10 tacked on to the gift, nothing would induce me to accept it.

It is a dictum among lawyers while estimating the value of a witness's evidence, to take into consideration two main points—first, his technical knowledge and practical experience of the subject at issue; and second, the value of his evidence as bearing on the case, and the amount of corroboration it will receive. So allow me to say, as illustrating the value of my own testimony on the first point, I never harvested 15 lbs. of surplus honey from a Ligurian stock yet, and the average amount would not be 3 lbs. per hive, while since my ligurianising experiences commenced I lost in one year nineteen stocks of bees out of a total of thirty-two hives from foul brood alone; and all this, as I must impress on my readers, happened, not because I was an enthusiastic rash-handed novice in apiculture, opening stocks daily, slinging right and left from combs containing unsealed brood, &c. (I never placed a comb in the extractor with unsealed brood in it) behaving as injudiciously as these young bee-keepers frequently do; nothing of this kind brought about my disasters, and yet Ligurians with me were a complete and thorough failure. Next week I will add the experience of some other bee-keepers on this subject in corroboration of my estimate of Ligurian bees.—W. B. C., *Higher Bebington*.

TRADE CATALOGUES RECEIVED.

Thomas S. Ware, Hale Farm Nurseries, Tottenham, London.—*Catalogue of Choice Hardy Perennials (Illustrated), and Lists of Chrysanthemums and Climbing Plants.*

J. Backhouse & Son, York.—*List of Alpine and Herbaceous Plants.*

J. Carter & Co., High Holborn.—*Catalogue of Farm Seeds.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspon-

dents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (Young Gardener).—The work you name is now out of print, and can only be obtained from dealers in second-hand books, or, failing this, possibly by advertising for a copy, but we believe it is not very readily procurable. (J. C.).—Our stock of "Vines at Longleat" is all sold. We do not know whether Mr. Taylor intends preparing another edition or not.

Dendrobium nobile not Flowering (M. H.).—As the plants grow well but produce flowers sparsely the pseudo-bulbs are probably not well ripened. After the plants have made their growth place them as near the glass as possible in a warm light house, only giving sufficient water to prevent the leaves flagging, and affording very light shade, and this only if needed to prevent scorching. Carry out this practice intelligently, and we think the plants will flower. From 1 to 2 fluid ozs. of petroleum well mixed in a gallon of water by constant and violent agitation will destroy scale on Camellias. It is not less effectual if mixed in a solution of soft soap or Gishurst compound.

Duke of Buccleuch Grape (J. M. B.).—We have never seen finer examples of this noble Grape than on Vines established on their own roots, but we doubt not that a healthy stock of the Muscat of Alexandria would prove a good foster parent for the variety in question. Mr. Dewar of Beechwood has found it to succeed well on West's St. Peter's, as one rod of the Duke inarched on that variety produced twelve bunches, the lightest weighing 2 lbs. 8 ozs., and the heaviest 4½ lbs. From one bunch the berries without the stalks weighed 2½ ozs.

Mushroom Beds in Shed (Uxbridge).—Mushrooms will grow equally well on flat beds a foot deep, or as ridges in a shed. With one bed 4 feet wide down each side of the shed you would have a bearing surface of 80 square feet; with lean-to beds 2 feet wide against the walls, and a central ridge 3 feet wide down the centre, the sloping sides of the ridges 3 feet high, you would have a bearing surface of 160 square feet; this, however, could be equalled by having two tiers of flat beds along each side of the shed, as is customary in Mushroom houses, one bed being on the floor and the other 2 or 3 feet above it in a strong wooden bin. The manure requires the same preparation whether it is to be formed into ridges or flat beds. These latter are not suitable for the open air unless they can be effectually sheltered from heavy rains.

Swarm of Insects (R. C.).—The insects forwarded belong to that common species *Julus terrestris*, one of the snake millepedes. This and other species in the genus, when they occur in gardens, feed both upon animal and vegetable substances. They devour slugs and snails, also soft-bodied insects, &c., and especially visit diseased or decaying roots. But as it seems to be undeniable that these millepedes will attack healthy plants, they must be placed upon the list of our garden foes. The bulbs of Lilies have been observed to be seriously damaged by them, also the roots of Primroses and Heartsease, and various vegetables, Potatoes, Cabbages, and Beans for instance. As the texture of the insect renders it hard to kill without using applications that are likely to damage plants, trapping them has been advised. Numbers will creep into little pots filled with horse-droppings or decayed roots, and they may also be captured by laying about scraped-out Potatoes and Apples.

Ribbon-border Arrangement (W. B. H.).—The flowers you have are sufficient for several combinations of colour. If the border is to be looked at from one side only, then begin in front with—1, *Cerastium*; 2, *Alternanthera*; 3, *Blue Lobelia*; 4, *Flower of Spring Pelargonium* with the flowers kept picked off; 5, *Pink Pelargonium*; 6, *Golden Bronze Pelargonium*; and 7, *Iresine Lindeni*, which gives a soft, chaste, yet lively combination of grey, carmine, blue, white, pink, dark brown and yellow, and deep crimson. Or for a bolder but equally harmonious effect take—1, *Alternanthera*; 2, *Cerastium*; 3, *Lobelia*; 4, *Scarlet Pelargonium*; 5, *Flower of Spring Pelargonium* with the flowers kept picked off; 6, *Iresine*; and 7, *Yellow Calceolaria*. But if the border stands out upon the lawn, and is approached from all sides, then there must be a balance of colour on each side in this way—a central row of pink *Pelargonium*, a row of *Flower of Spring Pelargonium* on each side of it, followed by rows of blue *Lobelia*, and with *Cerastium* outside; or yellow *Calceolaria* for the central row, *Iresine* on each side of it, *Lobelia* next, and *Alternanthera* outside.

Lime Water (W. H.).—It is immaterial what quantity of lime you use. If you place a lump weighing half a pound in four gallons of water that will be quite sufficient, and if you place in twice the quantity the lime water will be no stronger. If there is any sediment of lime at the bottom of the vessel it is proof that the lime water is strong enough, and as strong as it can be made. It must be used perfectly clear, and will then be quite safe for the majority of plants, and will bring out any worms that may be in the soil; but we hesitate to incur the responsibility of advising you to apply it to "Azaleas worth £8 a piece," as we have heard of its injuring Azaleas, and we should try its effects on a small plant or two of little or no value, and wait a few weeks for the effects before using to a number of larger specimens. Perhaps some of our readers who may have applied lime to Azaleas for eradicating worms will state their experience as to its efficacy and safety or otherwise. We do not remember receiving any soil from you; however, as your plants are doing well the omission is of no consequence. We shall be glad to see flowers of your Primulas. Embed them in a little damp moss, and send in a small wood or tin box, so that they may arrive fresh and uninjured.

Grafting Wax (F. J.).—There are various preparations used in grafting fruit trees. Some of the mastics require to be used warm, but the following may be prepared and used without being heated:—Yellow wax, 1 lb.; turpentine, 1 lb.; Burgundy pitch, 8 ozs.; mutton suet, 4 ozs. Melt all together
